The founding of Tenochtitlan historically belongs to the very late Postclassic time (AD 1345), and through history, it has been recognized as a large city almost comparable to Venice in Italy. This is why geography is very important when seating this group in time and place. Formed by a city sketched under a square pattern street and an agricultural system within and related to water. It even had public bathrooms at the end of its streets, which cleaned and utilized the solid waste for agricultural crops. Therefore, the types of native fruits and edibles varied accordingly to the geography.

The city of Tenochtitlan developed into a complex organization, which allowed for the construction of amazing temples and gardens, exotic animals, and an excellent cuisine. The increase in tributes or regalia allowed their economy to form a settlement pattern that incorporated

buildings, bridges, and streets along channels; boatmen in canoes made transportation a commodity to navigate from place to place. It is said that the bridges were so wide that ten horsemen could cross them abreast (Hofstadter 2005).

Although there is no record of what type of people were there before the arrival of the Aztec or Mexica, the type of people who built this city did not take long to build such a large and beautiful place that it amazed the Spanish. As they advanced in the making of the magnificence and efficiency of the city, they advanced geographically, incorporating two specific things: trade and tribute. In order to be in one end skillfully, and the other to keep a tradition, by allowing themselves to incorporate more gods such as Xipe Totec from the area of Oaxaca, although sometimes they humiliated their gods by placing them within the dark, designed to be their prison (Miller and Taube 1993: 24). They traded with the Pochtecas long distance and become commerce specialists as far as Guatemala and the Veracruz coast, leading the way for the Mexica to become an empire, struggle in battles, and defeat their neighbors the Tepanecs in 1428.

A key issue for understanding of power is that the Mexica replaced their traditional tribal administrative system of four heads with one *tlatoani*, who was the supreme ruler in political and religious affairs. As in many societies around the globe, the power was passed from father to son (as in the case of Motecuhzoma I to Motecuhzoma II); even though the system allowed for a new *tlatoani* to be selected by the council from one of hundreds of male nobles, it is believed by some that it was in practice blood related (Miller and Taube 1993: 168). Other sources contradict this idea (see Romero Vargas Yturbide (1959)) and support a dual political system based on both sexes, with females as innate administrators, while males could develop this skill, and either could be selected as a *tlatoani*. One known female was Ilancuetl, the first *tlatoani* from Tenochtitlan.

One of the amazing aspects of life, noted by the Spanish, was a type of baptism among the Mexica. This tradition consisted of removing any type of pollution from the parents and was more associated with purification. In the bath ritual, the midwife poured water from a vessel, placed on a reed mat, over the infant and was presented with the tools necessary for adult life. In the sixteenth century, the Mendoza Codex showed illustrations of a sculptor, feather worker, painter, and goldsmith, each accompanied by feathers and shields of a warrior. With illustrations of females came sweeping and cotton-spinning tools (Miller and Taube 1993: 44).

The Spanish conqueror Hernan Cortes describes in his accounts that they had a market where over 60,000 people could trade in goods. One of the rulers was known as Motecuhzoma II, who lived along with his retinue in one of the large palaces to the west of the city. The rest of the people lived in clans; the group of administrators were the *calpullis* and there were barrios or neighborhoods for foreigners and craftsmen.

The city of Tenochtitlan might have been founded under two different migrations of the Mexicas, led by Huitzilopochtli. Fray Bernardino de Sahagun recounts that this god was born in 1 pedernal AD 1168 under the *teomama* of Cuauhtlequetzqui. Then the Mexicas settled in Tullan, Atitalaquia, and Tequixquiac, and built the chinampas or *chinamitl*, which is an agricultural system based on a raised clay bed above a lake. It might be that originally, they were going to Coatepec, but there was a period of conflicts between Huitzilopochtli and the Mexicas. Huitzilopochtli ordered that all lakes and channels be dried up, so all native plants and animals perished, registered in the year 2 caña.

There is a large number of historical accounts about migrations. Migrations were not histories of people leading and leaving one physical space for another but of gods themselves who led the way for specific tribes.

An earlier migration, described also by Fray Bernardino de Sahagun, was based on the narration of the birth of Huitzilopochtli on a hill named Coatepec, located next to Tula. In this place, a woman named Coatlicue was the mother of the brothers Centzon Huitznahua and the sister Coyolxauhqui. The brothers were ashamed of their sisters to sacrifice through their special type of wartheir mother. Huitzilopochtli was born and helped the brothers to light up a snake made out of **teas**, called Xiuhcoatl, to wound Coyolxauhqui, who was then cut up in pieces up on the mountain and thrown down from it.

In Miller and Taube's account (1993: 94), Huitzilopochtli led his people into the valley of Mexico in Chapultepec at the end of the thirteenth century. As his people were unwelcome in the region, war was made among the neighbors, this time led by Copil, the son of Malinalxochitl, the betrayed sister of Huitzilopochtli left behind at Chicomoztoc. Later, Huitzilopochtli sacrificed Copil, and his heart was hurled onto a rock in Lake Texcoco, giving birth to the city of the Aztecs.

Years later, Huitzilopochtli was forced to lead his people to Culhuacan, on the other side of the lake, where the noble ancestors of the Toltec lived, and they become little more than slaves. Huitzilopochtli saw that this land was not their promised destination and that Tizapan had much more to offer. He suggested to the noble lords of Culhuacan that they ask their gods for a noble bride; in fear of the Aztec mercenaries, the lords complied, but the Aztecs flayed her, and a priest put on her skin. During a celebration for the arrival of a new goddess, they saw the priest wearing the princess's skin. The Culhua fiercely responded to the Aztecs' barbarism and forced the Aztecs to leave the lake. The survivors took refuge on an island, where they found an eagle sitting on a cactus growing from a rock – the very image Huitzilopochtli had told them to seek generations before. The migrations – or, as some authors call them, the wanderings of Huitzilopochtli – came to an end, according to most sources, in 1345, with the founding of Tenochtitlan.

Another chronicle called Mexicayotl gives an account that after leaving several towns, the Mexicas settled in Coatepec and Tula, along with the Chichimecas. The Otomies, being early occupants, allowed the Mexicas to **build** their temples and put their gods in them. Huitzilopochtli was the main god among them. The ball games, the *tzompantli*, and a dam to plant a variety of **cultivars**, water animals, and native trees gave way to the building of a large city.

The Ramirez Codex mentions the migration of the Mexica to Coatepec during the first pilgrimage, adding that they had a first division of the group in Michoacán and a second one in Malinalco; the rest arrived **at** Tula, settling on a mountain called Coatepec ("Hill of the Serpent"). The codex narrates the reasons why Huitzilopochtli got into conflict with his own people, as they wanted to remain in Coatepec after seeing the bountiful and prosperous life they had achieved, but this was against the desires of Huitzilopochtli, who executed them all by opening and eating their hearts.

Fray Diego de Duran precisely describes the reason why Huitzilopochtli killed and opened the chest of Coyolxau, the older sister of Coyolxauhqui and the brothers Centzon Huitznahua; it was because of their desires to stay and live in the beautiful place they had built and because they tried to convince Huitzilopochtli to stay there, provoking with this the drought of the channels and lakes they had developed into an agricultural system, achieving economic and social power.

Key Issues/Current Debates/Future Directions/Examples

Other chronicles such as those of Tezozomoc and Tovar repeat the same history. According to current debates, some authors state that Huitzilopochtli led his people out of Aztlán but to an unknown place located in the same region of Aztlán (Hofstadter 2005), and others suggest he led them to Coatepec (Miller and Taube 1993).

Geography becomes important for the discussion of these issue. For example, the Boutorini code makes remarks on the ethnic groups of pilgrimages by the *aztlameca* led by four *teteutiin* or *teomama*, who had specific names – Mixcoatl, Cuauhcoatl, Apanecatl, and Chimalma – glyphs, and functions according to the organization of the Tenochtitlan state. Each chiefdom of the Tenochtitlan state had its own war, tax and relationship with religion, a woman called Chimalma, as a priest – numen – two nephews and granddaughter, nieces and grandnieces, all relatives of Huitzilopochtli. Some authors argue that the name Chimalma is also a rivalry title among the descendants of Huitzilopochtli, related to rights to lands. Culhua rituals were addressed specifically to sacrifice daughters of the señores, or lords. Nonetheless, this aspect was amended by the Boutorini code, which addressed a change in

the political structure by the elimination of the feminine power, based on the historical and mythical events in Malinalco and Coatepec, marked by the killing of Coyolxauhqui.

Another example is based on the fall of Tula at the end of a period called the early Postclassic for the valley of Mexico. This event marked a change in the ethnic sociopolitical structure. Deities belonging to ethnic groups also changed their importance accordingly; for example, Quetzalcoatl in his representation as Ehecatl and Tlahuizcalpantecuhtli no longer had importance as Venus – in correlation with natural reproductive cycles. Also, Tlaloc is replaced with Xipe Totec, as a god related to earth fertility, and Xolotl, as deities belonging to dominated ethnias.

To understand the depth of the Aztec, a key issue might be a version that during the fifth sun, according to the legend of the suns, the fight between Quetzalcoatl and Tezcatlipoca, the death of Itzpapalotl by Mixocoatl, and the death of Coyolxauhqui all implicate the birth of Huitzilopochtli as the myth. Interestingly enough, a socioeconomic summit of Tenochtitlan occurred with the birth and life of Huitzilopochtli, as explained by an author under a materialist conceptualization, like the cycle of life, reproduction, cosmogony, and the necessary energy and sacrifice involved in it (Corona 1981: 22–25).

The legend of the suns was related to the first creation; each sun presided over a race of people, who were either destroyed or transformed into particular creatures. Tezcatlipoca was the god of the first sun; the people were giants who got devoured by jaguars. The second sun was presided over by Ehecatl, the god of wind; the people were destroyed by the wind and they became monkeys. The third sun was consumed by rain and lightning, presided over by Tlaloc, the rain god; the people became butterflies, dogs, and turkeys. The fourth sun was presided over by Chalchiuhtlicue; a flood transformed the people into fish. In the time of the fifth sun, Tezcatlipoca and Quetzalcoatl raised the heavens by transforming themselves into great trees. They created the earth by slaying a huge earth monster, described as a caiman deity called Tlaltecutli. Quetzalcoatl and Xolotl descended to the underworld to retrieve the remains of the people destroyed in the flood, tricking the god of death, Mictlantecuhtli. The bones were carried to Tamoanchan, where the gods ground the bones and added blood to create the flesh of the current race of people.

A compendium of books that allowed the Aztecs to receive various interpretations about their ethnic composition and certain aspects of their socioeconomic and political systems, pertaining to myths within chronological events, the magnificence of their settlement patterns to understand their religion, and the level of ideology as far as the dominium of a group within a state (Corona 1981: 13).

Likewise, the span and cult life under which the god Huitzilopochtli existed is a key issue in understanding the patrons, leaders, and long-standing lineages of the Aztec or Mexica. For example, the 18 *veintenas* of the Aztec calendar were based on festivals of primary agriculture dedicated to the rain and maize gods, but for four of those *veintenas*, the principal deity was Huitzilopochtli; a few other deities repeated, such as Xiuhtecutli and Tlaloque. The principal celebrations were feasts: feasts of merchants, small feasts for death, and bloodletting; for the second are amaranth tamales, feast of the *xocotl* pole; for the third deity including sacrifice to Xochiquetzal and other feasts for water deities (Miller and Taube 1993: 178).

Future Directions

Future directions and questions, are based in take initial departures related to migrations, cults, ethnic groups, and socioeconomic aspects of development in order that, separate, and/or join myth from history.

Cult study must incorporate the ideology of ethnic groups who went from adoring the sun, with Huitzilopochtli, to adoring the moon, with Coyolxauhqui, or both at the same time, but as it was Huitzilopochtli who allowed Coyolxauhqui to exist, what was the pervading sociopolitical situation that led Huitzilopochtli to destroy her? Was it based on the economic tribute or zones that gave less tribute to Huitzilopochtli because Coyolxauhqui was an older fertility goddess in Central Mexico?

One important matter to take into consideration is the time issue – how long it was before Huitzilopochtli allowed her existence, along with that of many other central gods, to come to decay within a controlled zone versus a time with less control and/or payment of tributes and regalia, on behalf of Huitzilopochtli.

Future studies might touch on issues based, for example, on the categorization of tributes or products that were handled according to the spatial and geographic distribution of ethnic groups. One of the key issues for such an endeavor consists of more closely analyzing the use of the sun calendar among the Mexicas and the large region it had an influence upon. Each linguistic group had different names for the 365-day calendar. Among the Mexica, it was called *xíhuiltl*; it was called *yza* by the Zapotec, *cuiya* by the Mixtec, and *Haab* by the Maya (Marcus 2000: 15).

Brief Definition of the Topic

Teotihuacan was a great metropolis during the Classic Mesoamerican period, and its importance and influence marked the political, ideological, and economic development of a great part of the

T

Central Mexican Plateau. The study of the city's architecture and town planning, as well as its internal and external social relationships, is key to understanding the cultural development of this culture. Fieldwork began with detailed mapping of the upstanding monuments, and a high-precision survey of pottery discarded on the surface (Millon 1973). This work aimed to discover as much as possible about the town without damaging the monuments or disturbing the strata by excavation. The pottery distribution proved very informative: the quantities recorded were displayed in the form of contour maps that showed the primary areas of discard (all pottery) and the areas of high-status residence (the distribution of the fine ware: regular thin orange) (Cowgill et al. 1984).

Investigations in the neighborhood of La Ventilla conducted since 1992 have identified a number of structures that are fundamental to understanding social relationships in the city; together, they make up the greatest area excavated and researched of any neighborhood in Teotihuacan (Fig. 1).

The neighborhood temple (4814 m^2) is defined by a block of houses of 60 × 70 m, integrated by three temples arranged around a central square (1). The Compound of the Glyphs (4758 m^2) corresponds to an elite monumental complex with political and administrative functions (1A). The residential compounds are defined as a group of houses and workshops mainly involved in lapidary and shell working (3). Between the two elite complexes and the compound of artisans is the Public Square, an area of more than a hectare, without any apparent buildings (2).

The excavation in La Ventilla follows the parameters set by the *Teotihuacan Mapping*

Teotihuacan (La Ventilla): Field Method, Fig. 1 *1*. Neighborhood temple, *1A*. Compound of the Glyphs, *2*. Public Square, *3*. Residential compounds, *4*. Living quarters, *5*. Streets that surround the departmental compounds

Project (Millon 1973). The general grid, oriented towards the Teotihuacan north, is divided into 1 m^2. The wide area of excavation will allow us to study the full extent of a neighborhood in detail.

All the archaeological strata and objects are excavated stratigraphically and located in three dimensions. Except in cases that merit it, the excavated area is backfilled once all the information has been recorded. The study of the different materials is conducted in specific areas and labs allocated in the archaeological area, although the support of other Mexican institutions, according to arrangements of the Archaeological Council of the National Institute of Anthropology and History of México, is also fundamental.

Introduction

The city of Teotihuacan is located in the northeast part of the Valley of Mexico. It is delineated by the Cerro Gordo and Cerro de Malinalco to the north, Cerro Patlachique to the south, the Cerro de Cuautlancingo to the east, and Cerro de Tlahuilco to the west. The Teotihuacan Valley contains approximately 600 km^2 of land area and is located at a height of between 2,240 and 2,300 m above sea level.

Definition

Teotihuacan was an essentially urban culture, a multiethnic society arranged according to a precise model of town planning, linked by family relationships and lines of descent (Millon 1973). However, beneath this is concealed a series of complex questions on sociopolitical organization and integration, within a single urban space over six centuries of cultural development. Over the last few years, scholars have drawn attention to the multiethnicity of the inhabitants of Teotihuacan, which is demonstrated by the different ethnic quarters found in the city. During the classical period, the city contained almost 80% of the population of the Valley of Mexico. However, the rural population experienced exponential growth and had a tendency toward small settlements located throughout the territory (Sanders et al. 1979).

The Pyramids of the Sun and the Moon that are located in the central area of the city are understood as an expression of religious, political, and ideological power (Fig. 1). In addition, a political administrative area has been identified southeast of the archaeological area. This is the magnificent collection of the Citadel and contains the Temple of the Feathered Serpent. Control of the production of green obsidian from the Sierra de las Navajas (Hidalgo) had a decisive role in the expansion of the city (Spence 1981).

Key Issues

Teotihuacan provides an opportunity to study a densely populated, long-lasting city with inhabitants of various origins. This scenario leads to a number of questions regarding the way the city was organized and governed and its expansion across Mesoamerica. While it cannot be said that

Teotihuacan: Geography and Culture, Fig. 1 Pyramids of the Sun and the Moon photo by Miguel Morales INAH-ZAT

Teotihuacan is where the Mesoamerican city was "invented," we can say it is where it achieved a high degree of complexity.

There are various interpretations as to the origin of Teotihuacan. In a process of cultural consolidation, these can be grouped into the Altiplano Late Preclassic period, the successive volcanic eruptions that occurred in the Altiplano and the Valley of Mexico, and the subsequent movements of people who would find the Teotihuacan Valley to be not only a habitable but also a religious place to live (Sanders et al. 1979: 106–107; Angulo 1997: 147; Carballo and Pluckhan 2007; Uruñuela and Plunket 2007). However, we should remember that it is not easy to find early traces of occupation and urban growth due to the way the city itself was constructed, which involved constant architectural restructuring and alterations to the evidence in situ. The Tzacualli (1–150 d.C.) and Miccaotli phases (150–200 d.C.) indicate a society with well-defined cultural complexity. However, its political forms of organization are difficult to interpret due to the apparent unwillingness of the Teotihuacanos to highlight individuality. This characteristic differentiates them from their contemporaries such as the Mayas, whose governing elite maintained a public program that depicted their triumphs and established their legitimacy along with personal and family successes and their links with ancestors and the gods. Rather than a royal dynasty, in Teotihuacan we should imagine a tightly knit elite group which superimposed a corporate model for exercising power onto individual interests that were established along family lines of descent (Fig. 2). Research into this corporate model has been carried out by various scholars, with some outstanding work being produced by Linda Manzanilla (2006).

The Tlamimilolpa phase (200–350 d.C.) provides a clear example of a far-reaching program of architectural reorganization for the city, though this is not exclusive to the Classic period. This architectural reorganization can be seen from research carried out in caves to the east and southeast of the Pyramid of the Sun, which show the use of quarries and a large-scale post-Teotihuacan process of reoccupation, altering earlier signs of construction (Moragas 1995; Manzanilla 2006). One of the questions that arise concerns when the town planning model of the Late Preclassic period in the Valley of Mexico changed to the multifamily model that took shape in Teotihuacan during the Classic period. During the Late Preclassic period, each group of housing followed some common patterns (Fig. 3). Many Teotihuacanists believe that during this period each local district became the center of socioeconomic and ideological activity for groups of families linked by a

Teotihuacan: Geography and Culture, Fig. 3 Yayahuala complex photo taken by Miguel Morales INAH-ZAT

common origin. However, this emergent model can be connected to the city's expansion and the consolidation of the Teotihuacan town planning model, which broke with the previous socioeconomic structure found in the Valley of Mexico, as demonstrated by Manzanilla in a research she carried out in Cuanalan. The same pattern occurs in the structure of Teotihuacan domestic organization if it is compared with that of the Maya (Cowgill 1997; Manzanilla 1985).

The Xolalpan phase (350/400–550 d.C.) shows the consolidation of all aspects of Teotihuacan culture. The presence of Teotihuacan in Mesoamerica expanded during this period. This has been interpreted as the success of the Teotihuacan model and therefore is associated with cultural success and growth. A competing interpretation is that, on the contrary, this expansion was due to the migration of certain groups from the city to live outside of the territory that was under the control of the city and that this was the first evidence of a profound crisis that led to the collapse of the city (García Chávez 1998).

The Metepec phase (550–650 d.C.) encompasses the collapse of the city. There have been a many different explanations for the fall of

Teotihuacan. They can be grouped into two general lines of interpretation: internal reasons (sociopolitical crisis) and external reasons (ecological-invasionist crisis). These interpretations attempt to identify the key factor that triggered the events that lead to the collapse of the city and the consequences of this for the surrounding area. Although it should be recognized that a single factor will not explain the collapse of Teotihuacan, it is also true that interpretations pointing to multiple causes are not completely satisfactory as they meet the same problem of having to identify an initial factor that prompted the great final crisis. The collapse phenomenon, therefore, also needs to be reassessed from other perspectives, not so much to find its immediate causes but to characterize the different processes that emerge from each study of the case. Some elements that need to be included in a nuanced understanding of the collapse of Teotihuacan include social stratification, the presence of Coyotlatelco culture inside the city during Teotihuacan times, and the contraction of the Teotihuacan state during the Xolalpan phase (Moragas 2005).

Terp Excavation in the Netherlands

Johan A. W. Nicolay
University of Groningen, Groningen, The Netherlands

Introduction

Before the first sea dykes were constructed in the twelfth or thirteenth century CE, the coastal area of the Northern Netherlands was dominated by extensive salt-marsh. Habitation in this unstable maritime landscape was concentrated on relatively high ridges, often along tidal gullies. Because such ridges were still subject to flooding several times a year, people had constructed artificial dwelling mounds or *terps* (in Dutch: *terpen* or *wierden*) from the first colonization of the salt-marsh area in seventh century BCE. They started

with one or more small house platforms, which were gradually raised and extended with layers of sods, dung, and trash. The present-day terps, often still clearly visible in the flat landscape, represent the final phase of their development. Although being constructed for a different reason and in a different landscape, terps can be compared to *tells* in the Eastern Mediterranean, also comprising many overlapping habitation layers that may cover a period of several thousand of years at the same site.

Key Issues/Current Debates/Future Directions/Examples

The current method of excavating terps was largely developed during a research project at the site of Wijnaldum-"Tjitsma," in the northwestern part of Friesland (Besteman et al. 1999). Following the discovery of an 17 cm long, gold disc-on-bow brooch (c. CE 600), the universities of Groningen and Amsterdam joined forces to get a better understanding of the archaeological context of this exceptional, probably royal find. Between 1991 and 1993, a total of 8000 m^2 was excavated, 7% of the terp's total volume. This project pioneered a new strategy, which involved *stripping* with a mechanical excavator, the systematic use of a *metal detector* (resulting in the unprecedented number of c. 5000 metal finds), and *wet screening* (e.g., resulting in the discovery of gold drops, sherds of glass vessels, and numerous fishbones).

A cross of two areas was opened, measuring 210 × 76 m. The top soil was removed by a mechanical excavator in layers of 5 cm or less at a time and the surface checked for metal finds with a detector. The first archaeological horizon generally appeared at a depth of 40–60 cm below the present ground surface, whereupon it was cleaned by hand, drawn, and photographed (Fig. 1). All *negative features* and *sod-walls* were *sectioned* and documented, and the soil from all features was wet screened with a mesh width of 4 mm. Organic- or find-rich features were also sampled for zoological and botanical remains. This process was repeated at the next level, which was usually

Terp Excavation in the Netherlands, Fig. 1 Excavating a horizontal level at the terp site of Wijnaldum-"Tjitsma" (Friesland): After the top soil is removed with a mechanical digger, the archaeological level is cleaned using a flat shovel, revealing the outlines of features cut into the clayey soil. Today, precision machining with a grading bucket may leave a surface clean enough to excavate. (Photo: University of Groningen, Groningen Institute of Archaeology)

20–25 cm below the previous one. Locations of exceptional finds, like sherds concentrations or human and animal skeletons, were examined in greater detail.

Some reflections on this methodology suggest future developments. The recording of the site using the *planum method* has the disadvantage of disconnecting finds and features belonging to the same cultural layer and disconnecting the horizontal horizons and the vertical sections, since these are recorded separately. The Wijnaldum experience showed that such links can only partly be made afterwards, even by using three-dimensional reconstructions of digitized drawings. Ideally, the original surface of the cultural layers should be excavated, and recorded in three

Terp Excavation in the Netherlands, Fig. 2 Recording a "free section" at Anjum (Friesland). Interfaces between layers are outlined on the surface of the cleaned section and labeled, before being recorded with written descriptions, measured drawings, and photographs. Objects disturbed or located by metal detector are assigned to their layer of origin. The stratified sequence seen in section provides a basic narrative for the occupation of the terp. (Photo: University of Groningen, Groningen Institute of Archaeology)

dimensions. In practice, large-scale terp excavations have already become too time-consuming and too expensive to encourage the extra burden of stratigraphic excavation.

One new research method that is economic and effective makes use of existing sections already cut through known terp sites. Between 1840 and 1945, about two-thirds of all terp sites in the Northern Netherlands were completely or partly dug away, to be sold as humus to enrich the sand and peat soils in the hinterland. These sites can be investigated by cleaning the escarpment of the surviving intact mound (Fig. 2). In this way sections of 100–200 m long and 3–4 m high can be studied in only 4–5 weeks without eroding the remaining terp. Added to the results of "traditional" excavations, these *free sections* give valuable insights into the structure, chronology, and conservation of terp sites in different parts of the Northern Netherlands (see Nicolay 2010).

Terracotta Architectural Sculpture in Classical Archaeology

Patricia S. Lulof
Amsterdam Archaeological Centre, University of Amsterdam, Amsterdam, The Netherlands

Introduction

In Central Italy, hardly anything survives of the buildings and temples, except for the stone foundations and many tons of architectural terracottas. Easily broken and damaged, the decoration had to be replaced frequently, with styles that varied

throughout the different regions of Etruria, Latium, and Campania. Each area had important centers for the production of architectural terracottas and even entire roofs, and exported these to different sites by sea.

To protect the wooden superstructure of houses and temples from weathering, architects adopted the Greek invention of terracotta roof tiles and antefixes to cover and embellish the sloping roofs, revetment plaques to cover horizontal beams, and simas for the raking pedimental and lateral elements. The end of the gables remained open, thus creating space for small pedimental roofs with additional tiles and antefixes. Indeed, the roofs of Etruscan buildings were among the most complex and decorative in the ancient world. Private houses too were regularly adorned with decorative terracotta roofs, although from the middle of the sixth century BCE onward, only temples or public buildings were given decorated roofs. One of the many particular features of Central-Italic architectural decoration that distinguishes it from that in mainland Greece is the presence of figural decoration in the pediments and on the roofs themselves, in the shape of acroteria and ridgepole statues.

Key Issues/Current Debates/Future Directions/Examples

Terracotta Roofs in Etruria

The earliest roofs known to us today had only painted decoration with mould-made elements such as small antefixes with female heads. This early phenomenon appeared primarily in Etruria, mainly at Murlo, Acquarossa, and Tarquinia. In the early Archaic period up to the end of the sixth century BCE, Southern Etruria, with Caere and Veii, seems to have been predominant in producing roofs and roof decoration, Caere being the first center working in a specific Ionian style. This style coincided with the so-called First Phase roofs with mould-made decoration using figural scenes and antefixes with gorgon masks or female heads. During the sixth century BCE, the simple female head was by far the most common type used, with several different types datable to the second half of the century, mostly coming from Caere. The female-head antefixes were very popular, their moulds being much used, varied, and altered. This was not only because of their attractiveness, but also undoubtedly because of the power of the image as such. Their significance must surely be connected to the goddesses venerated in the temples they decorated, who were represented by images of nymphs, priestesses, or perhaps even by an image of the goddess herself. Popular especially during the second quarter of the sixth century BCE were military scenes of departing warriors or armed riders, but later such scenes more commonly included banquets, processions of chariots, and, for the pedimental slopes, chariot and horse races. The open pediments were given reliefs, protecting and covering the ends of the *columen* and *mutuli*. The lateral corners of the roof, as well as the *apex*, were usually given decoration in the shape of acroteria, terracotta sculpture in-the-round. In Etruria especially, the ridgepoles were decorated with abundant terracotta statuary.

Terracotta Roofs in Campania

Overlapping to a degree, but certainly by the end of the sixth century, Campania, with centers like Cumae and Capua, seems to have taken over the market with an especially popular but short-lived roof system, with antefixes set in tongue frames and revetments with floral elements like hanging palmettes and chains of lotuses. The first *columen* and *mutulus* plaques derive from the Campanian system. Modest acroteria in the shape of sphinxes, disks, or single winged figures were placed up on the roof. This style was adopted all over Central Italy, only to be copied and in the end replaced by the local styles and techniques of traveling workshops in Latium; there, local styles and techniques dominated the area until 480 BCE. It is called the Second or Late Archaic Phase, beginning in the last quarter of the sixth century BCE and showing a marked change in the style of the decorative system. This was influenced by the Campanian system, with floral elements replacing figural scenes, and large antefixes with female heads or gorgon masks surrounded by tongue frames slowly developing into entire figures or pairs of

figures up to a height of half a meter. The format of the revetment plaques for the pediments and the lateral sides of the buildings was also enlarged with tall tongues above a flat painted frieze with meander or *guilloche*, under which there was a moulded frieze with palmettes and lotus flowers, or *anthemion* chains linked by volute bands. The pediments were filled with large *columen* and *mutulus* plaques showing hand-made reliefs with figural and mythological scenes. On top of the roofs appeared large statues of gods and warriors, set in pairs or in otherwise complex scenes. This completely new style of revetment was introduced in conjunction with the development of larger temple architecture and continued well into the fifth century BCE. By then, only temples were given these rich decorative roofs.

Terracotta Roofs in Southern Italy

Archaic architectural terracottas from Southern Italy and Sicily are famous for their richness in quality and quantity, and their "transitional" position between the terracotta roofs of mainland Greece and those of Central Italy. It is said that they represent the best of both traditions, showing a rich variation in painted decorative motifs and a fully fledged Greek-oriented styling. Both Sicily and Southern Italy employ two different and incompatible roof systems, one with lateral simas along the eaves and a second with antefixes and eaves tiles. The system using antefix plus eaves tile seems to have been cheaper in production than that with lateral simas along the eaves, and was said to have originated in northwestern Greece. It was particularly popular for modest buildings, such as small temples, *naiskoi*, and grave monuments. Southern Italy in particular quickly adopted the idea of decorative antefixes with eaves tiles for its buildings. These antefixes are invariably combined with horseshoe-shaped cover tiles and a hybrid roof system with flat pan tiles. For the Tarantine antefixes, this has not always been the case. Circular antefixes were used also to cover the *kalypter* in the pediment of small temples. The prime period of production in Southern Italy started around the middle of the sixth century BCE. It continued, especially in the main production center of architectural terracottas in Tarentum, well into the fourth century BCE. The main source of influence on roofs and their characteristics (antefixes and simas) came from Asia Minor (Ionia). Through Sicily its influence permeated into Southern Italy. Corfu, on the other hand, had a direct influence on the production of antefixes in Southern Italy, at Sybaris, Lecce, and Tarentum. After about 550 BCE, both Sicily and Asia Minor seem to have been dominant in influencing the typology in decoration and images in Southern Italy.

Terracotta Roofs in Italy, After 500 BCE

By the end of the Archaic period, this new roof system had developed in Central Italy that was exclusive to religious buildings. The change of political rule, the dominance of Rome, and the impulse from Greek immigrants from Southern Italy, all contributed to influence this process. This new system is known as the Second Phase. The roofs of private houses and elite buildings were no longer given terracotta decoration. Temples grew larger and more monumental than before, and their roofs became more elaborate and complex. The dimensions of each individual roof element became larger, with antefixes, for instance, reaching heights of about half a meter. Large terracotta sculpture was placed on the roof. Reliefs in the open pediments which covered the ends of the beams grew larger, and carried mythological figures and scenes that almost completely filled the pediment. Revetment plaques and raking simas were given floral decoration instead of figural scenes and became more complex in construction. This new style with full-figure antefixes became popular and the most common decoration was a group of dancing satyrs and maenads, *Mischwesen*, along with full-size heads of mythological figures and goddesses. Around the middle of the fifth century BCE, the centers of central and inland Etruria gained in importance at the expense of the coastal cities. Orvieto and Cività Castellana in particular became large production centers for roofs. The models from these workshops spread over a large area, including cities such as Arezzo, Perugia, Talamone, and Tarquinia. This development into monumentality on a large scale continued in the periods after the fourth century BCE, at pace with the revival of the Etruscan centers after a short period of decline.

The previously inset roofs placed on the floor of open pediments (the recessed gable) that had formed part of Archaic temple architecture gradually disappeared, to be replaced by fully fledged pedimental groups set against a closed background. The first of these appeared in Rome itself and is dated to the end of the fourth century BCE. During the Classical period, decoration consisted of large heads of satyrs and females surrounded by large concave frames decorated with floral motifs in relief which alternated along the eaves of large temples. For smaller buildings or for use on the floor of recessed gables, smaller heads surrounded by a frame of long, concave tongues continued to be used, and heads wearing floral wreaths became very popular. In contrast to the nymphs of the Archaic period, the female heads now represented maenads. They were accompanied by heads of satyrs identifiable by their animal ears, and characterized by their ivy wreaths or frames with ivy and bunches of grapes as followers of Dionysos. The same types continued into the fourth century and the Hellenistic period, the heads reflecting contemporary styles of sculpture. Third-century terracotta production was strongly influenced by the destruction of two important Etruscan sites, Volsinii (264 BCE) and Cività Castellana (241 BCE), and by the foundation of the Roman colony in Cosa (273 BCE), where a new important production center of roofs was set up. Subsequently, it was in the newly reinforced Latin colonies everywhere in Northern and Central Italy, where the organized urban centers were provided with temples of the Etrusco-Italic type. With the rich decoration of their pediments and mould-made elements, they represented instruments of Roman propaganda. In the following period, between the third and second centuries BCE, when Roman Italy was itself being constructed, Etrusco-Italic temples and roof systems, and their figured terracotta decorations were true *fictiles fabulae*. Placed in a program of renovation that was especially important for the local elites, they underscored the people's Roman citizenship. This period was marked by a strong economic and cultural renewal, when Etruscan cities like Falerii, Telamone, Cosa, Vulci, Luni, and Cività Alba commissioned monumental temples with rich pedimental decoration in terracotta. The pediments were filled with statuary groups, taking Greek-Hellenistic pedimental sculpture as an example of style, composition, and *themata*. The scenes displayed were quiet scenes of standing or seated figures from the pantheon (like the myths of Ariadne and Andromeda), or complex scenes from legendary wars and fights, complete with chariots, horses, and monsters (like scenes from the Trojan War or the Theban cycle). Often these scenes represented actual wars and victories, and had a strong political impact.

Terracotta Roofs in Roman Italy

Romanization forged ahead throughout Central Italy influencing the imagery and quality of the old Etruscan models in roof decoration, replacing it slowly but surely by a standardized Roman roof system. In the more southern regions, especially in Campania and Lucania, the decoration of temples was more modest in comparison to that of the temples in Etruria and Latium, the only images used being those in antefixes of a Campanian type with female heads and revetment plaques with Medusa heads. The final monumental stage in the development of architectural decoration was reached in the second century BCE, with the introduction of some new types of antefixes, mostly *Potnia Theroon* antefixes and antefixes with heads of Athena. The closed pediment was now apparent everywhere; its complex and rich statuary groups changed the overall appearance of the temples, fully providing them with Roman political propaganda and a frontal aspect of prime importance. Themes reflected historical events in religious and mythological contexts. It has been called the "Latin triumphal art" and was executed in the Hellenistic, "Neo-Attic" style, a *koine* in an artistic sense, which was omnipresent and dominated the whole of the Mediterranean world. In all Italic territories, architectural terracottas became widely distributed, both in the areas surrounding the great cities and in many distant places on the peninsula. In Roman times, the terracotta decoration of temples was still much admired. Pedimental decoration in terracotta was visible both in Rome itself as well as in provincial towns Architectural terracottas from the Roman period are plentiful, but in comparison with roofs from the Archaic, Classical and

Hellenistic periods, they are much less complex in variation and type. The Etruscan tradition of protecting and decorating temples with terracotta elements was slowly abandoned in favor of the embellishment of public and sacred buildings with stone and marble. Large antefixes disappeared altogether. The dominant production centers of architectural terracottas Città Castellana and Orvieto diminished in importance, and production returned mainly to Rome, where workshops developed new models of Hellenistic origin. Greek artists and artisans dominated the artistic scene and production from the second century BCE onward. They acquired complete autonomy and distributed their products throughout the whole of Central Italy and beyond. One group is predominant, the revetment plaques of the "Campana" type which were produced from the first century BCE onward and which by far outweighed the production of other roof decoration and decorated the exterior of sacred, and other public buildings, as well as private ones, such as villas. Roman antefixes have not received so much attention as "Campana" reliefs, probably due to their simplicity and modest artistic value. Their dimensions are small and their figural motifs limited. Medusa seems to have remained a popular type for both antefixes and other revetments in the Roman period. Production reached its peak in the Augustan and Julian-Claudian periods, coinciding with the explosion in building activities in the early imperial period. Decorative architectural terracottas became unusual after Imperial times, after the second century CE; marble was preferred then everywhere over decoration in terracotta.

Technique and Manufacture

A mould or *matrix*, like no other object in terracotta, informs us about both the production process and the distribution of architectural terracottas in Antiquity. Moulds were used to produce decorative elements when several were needed: raking and lateral simas, antefixes, or revetment plaques. They show the first phase of the creation of parts of the roof decoration, as well as the reproduction of other elements. Moulds were important tools for coroplasts, enabling them to reproduce hundreds of roof elements of the same quality at the same time, as well as enabling distribution over a vast region. Moreover, creating new moulds of existing revetment plaques or antefixes made it possible to use one type of roof decoration over several generations. Moulds are rarely preserved. Not many workshops producing roofs have been located during excavations, so the chance of finding workman's tools is relatively small. It also seems that moulds were not thrown away immediately but kept in use for a long period of time. They were sometimes even repaired. Today, some twenty moulds for antefixes and a few for relief plaques or other roof parts are known, namely, those from Città Castellana, Orvieto, and Capua. Only in one case, that of the Amsterdam mould Cat. no. 36, was a cast ever found during excavations, although some casts seem to have derived from the same type. Reconstructing the production process of terracotta objects is relatively easy, since working in clay has not changed over the centuries. The process of the creation of a mould and its subsequent use is as follows. The perfect model or *patrix*, created by a master coroplast, was covered with wax or oil after firing. Then a thick layer of soft clay was pressed over the *patrix*, thus creating a copy in negative, a mould. Presumably the same clay was used for both moulds and final products. After drying, the mould could easily be taken apart, thanks to the oily layer dividing it from the model. The mould was cut into a manageable format. Thus, all details of the model were copied in the mould. Sometimes extra details were added to the final product, but the moulds we know are all very detailed as regards hairdo, facial features, and decoration. After using the mould for the production of, for instance, the antefixes of a roof (a single mould could be sufficient), they were slipped, and then painted with a mixture of slip and natural pigments such as iron oxides and calcium. The products were fired between 800 °C and 1050 °C, thus fixing the colors to the surface so as to withstand the weather. In this way, some colors have been preserved right up to the present day.

T

Terramara Santa Rosa di Poviglio Alluvial Site

Mauro Cremaschi
Dipartimento di Scienze della Terra 'A. Desio', Università degli Studi di Milano, Milan, Italy

Introduction

The "Terramare" are banked and moated villages dating to the Middle and Recent Bronze ages

(1600–1150 year BCE), located in the alluvial plain of the Po river, northern Italy. They are witness to a complex society, whose subsistence was based on intensive agriculture, pastoralism, and long-range trade (Barfield 1994). The Terramare people first carried out a radical clearing of the Po plain to provide land for intensive agriculture, and changed the natural drainage by digging canals and ditches to feed moats surrounding the villages and to irrigate the fields in the countryside (Cremaschi et al. 2006). The culture reached its apogee, along with a prolific population, at the beginning of the Recent Bronze age, but at the end of this period suffered a societal collapse that led to the abandonment of the villages in a few generations (Cardarelli 2010).

Key Issues/Current Debates/Future Directions/Examples

The Terramare have been a major subject of research by the Italian pioneers of prehistoric archaeology (Pearce 1998), but had been neglected for at least sixty years, and were thought to be almost destroyed by quarrying for soil during the nineteenth century. But at the beginning of the 1970s, geomorphological mapping of the Po plain, using aerial photography, demonstrated that the Terramare had largely survived quarrying. From that period onward, several projects have marked a new stage in their study (Bernabò Brea et al. 1997).

In the framework of this renewed interest, the archaeological excavation of Santa Rosa took on the task of extensively exploring a Terramara village, with the explicit aim of shedding light on its architectural structures and its development over the 400 years that the village lasted. The Santa Rosa site was selected by virtue of its good state of preservation and because it was threatened with destruction by agricultural work. The site was defined by aerial photography, which revealed its limits in outline (Fig. 1a). Subsequent geophysical survey showed up areas of high and low conductivity, indicating areas dominated by wet and dry features (color coded on Fig. 1b). The interpretation is of two settlements, each surrounded by clay ramparts and moats.

Excavation has been carried out under the aegis of the SoprintendenzaaiBeniArcheologici of Emilia Romagna and the local authority, and performed by a professional team, which also trains archaeology students for the principal research institution (University of Milan). The

Terramara Santa Rosa di Poviglio Alluvial Site, Fig. 1 The Terramara Santa Rosa as seen on the aerial photograph (*left*) and on the base of near-surface geophysical prospection (*right*). Aerial photograph: *1* – small village; *2* – large village. *Yellow lines* delimitate the areas excavated up to now: (**a**) area in the small village 1984–1992; (**b**) area between the two villages 2008–2011; (**c**) area in the large village and in the moat 1993–2011. Geophysical prospection: *blue colors* indicate conductive media (*clayey deposits*) indicating moat ditches and flood deposits surrounding the site; yellowish/reddish colors indicate resistive media (*sandy-silty deposits*) putting in evidence the Terramara shape (Mele et al. 2011)

Terramara Santa Rosa di Poviglio Alluvial Site, Fig. 2 The area excavated in the large village. The buildings, indicated by clusters of post *holes*, are delimited by peripheral moat. Note the high concentration of *circular wells*

aims of the excavation are to map the detailed occupation of the larger (7 ha) settlement and explore the relationship between the two. The first 28 seasons have opened an area of 1 hectare, revealing the defenses, post-rows of buildings, and numerous wells (Bernabò Brea and Cremaschi 2004; Fig. 2). The excavation period is limited to the summer season; during the winter/spring seasons, the water tables rise very close to the ground surface, make digging difficult (Fig. 3).

The original settlement was built at the edge of the Po river during the Middle Bronze Age, and consisted of a group of rectangular houses on piles protected by a timber palisade. At the beginning of the Later Bronze age, the Terramara reached its maximum expansion with the construction of the large village. Inside it, the houses were still on piles, but arranged along specific alignments and organized into quarters bounded by roads going through the village and crossing the surrounding moat over wooden bridges thereupon reaching the countryside (Cremaschi and Pizzi 2011). At the end of the Late Bronze Age, the village underwent a radical renovation: the houses were no longer built on piles, but rested on the ground according to the block-house technique. The peripheral wooden fences were replaced by massive earth ramparts.

The region in which the Terramare previously flourished was abandoned for at least five

Terramara Santa Rosa di Poviglio Alluvial Site, Fig. 3 Archaeologists at work in the course of a field season in the Terramara Poviglio Santa Rosa

centuries. The Santa Rosa village area became a mound, covered with forest and surrounded by marshes which colonized the former ditches. It was settled again only in the sixth century BCE by Etruscan colonists.

Textiles and Fabrics: Conservation and Preservation

Ulla Mannering[1] and Irene Skals[2]
[1]The Danish National Research Foundation's Centre for Textile Research, The National Museum of Denmark, Copenhagen, Denmark
[2]Department of Conservation, The National Museum of Denmark, Lyngby, Denmark

Introduction

A textile is a binary system of fibers or other materials worked into threads. In essence a textile

is formed by weaving, but the term can also be used more generically and thus covers flexible products made in other techniques, as, for instance, twining, needle binding, knotting, and knitting. Felting and basketry are also techniques related to textiles. Thus, textiles can be seen as one part of an overall cloth culture, which may include many different materials and techniques (Harris 2012).

Around the world and throughout time, humans have created textiles by exploiting different natural resources and inventing tools and methodologies to change these resources into a viable product. Some areas are rich in traditional textile resources, like materials for fibers, dyes, and tools, but also in less resource plentiful areas, humans have found solutions for fulfilling the demand for textiles.

Definition

Until very recent times, textiles were primarily made from natural fibers of either plant or animal origin. The most well-known plant fibers are flax, hemp, nettle, and cotton, while the most well-known animal fibers are sheep wool and silk. Like any perishable organic material, these fibers are subject to rapid decomposition in archaeological contexts, and their preservation requires special conditions to prohibit their destruction by microorganisms.

Key Issues/Current Debates/Future Directions/Examples

Contexts

Environmental conditions affect the survival of plant and animal fiber materials in various ways. In general, an acidic environment favors the preservation of proteinaceous fibers, while a alcaline environment does the same for fibers of vegetal origin. As most degradation requires the presence of air, many textiles have been found in contexts where anaerobic and/or waterlogged conditions occur. Other conditions like extreme dryness or permanent frost; the presence of salt; exposure to fire, which leads to the creation of carbonized samples; or through mineralization when coming into contact with metal salts have also preserved many textiles.

The find context influences the preservation of archaeological textiles. In Europe, most textile remains have been found in connection with burials, such as costumes, wrappings of human remains and/or grave goods, furnishing, and other utility textiles. In inhumation graves, the organic materials are often exposed to heavy and fast degradation, and, in most cases, it takes special conditions as, for instance, the presence of metal salts from copper or iron to prevent the degradation (e.g., Bender Jørgensen 1992; Rast-Eicher 2008; Gleba and Mannering 2012). Though these textiles are often very small and in a stage where further organic analyses are excluded, they still offer due to their number and firm structure an important source to European textile technology. In dry climates as in Egypt, many textiles have been preserved by desiccation and aided by the burial custom of embalming the dead. In a similar way, the special tradition of embalming and placing the dead in caves, which was performed in the pre-Columbian Inca kingdom, has preserved many colorful textiles made of cotton and wool in South America. Frozen environments like the Norse burials in Greenland have left fabrics almost unaltered, and in the recent years, the melting of glaciers in, for instance, Switzerland and Norway have also revealed well-preserved textile finds. In Denmark, the waterlogged, anaerobic, and acidic environment in burial mounds has favored the preservation of a large collection of complete Bronze Age textiles and costumes.

Other important contexts where textiles may occur are settlements, harbor areas, garbage dumps, and earth fillings. Many excavations in medieval towns around Europe have revealed new and important textile corpuses that supplement and challenge information based on written sources, and also textiles found in churches and relics provide important perspectives to our textile history. Especially in Northern Europe, many textiles have been found in connection with ritual offerings, as in weapons deposits, or together with mummified human remains. From these

lake and bog contexts, many complete wool textiles and other objects made of skin and fur dated to the Iron Age have been preserved. Until recently, it was believed that this acidic environment in the North European high bogs only favored preservation of proteinaceous origin, while it was only larger objects of plant origin like cords and ropes made of tree bast, stems of flax, and wooden objects that could be preserved in bogs. Nevertheless, during the reexamination of the Huldremose Woman (Fig. 1), the last remains of a textile in plant fiber was discovered on her back, and threads from this weave could also be located in many folds in her skin (Frei et al. 2009). This is the first time that a plant fiber textile has been recorded from a bog context in Denmark. This example shows that although a specific context and environment in general favors a specific material, every archaeological find is in itself unique. When excavating new finds or researching already excavated finds, it is important to be open for all possibilities in order not to overlook important archaeological materials.

Textiles and Fabrics: Conservation and Preservation, Fig. 1 The Huldremose Woman's costume consists of two skin capes, a woven skirt and a scarf in wool, and an undergarment in plant fiber. The woman and her fantastic well-preserved costume were found in a bog on Djursland in Denmark in 1879 and belong to the National Museum of Denmark. The find is 14C dated to 350–341 BCE

The scarcity and poor preservation of archaeological textiles are two factors usually cited for the absence of focus on textile studies. Although valid to a certain extent, such reasoning has obscured the fact that textiles are much more abundant in archaeological contexts than generally assumed and should, whenever present, be studied in the same way as any other archaeological finds.

Textile Research and Scientific Analyses

Textiles have an enormous potential in archaeological research, being able to tell about social, chronological, and cultural aspects of past societies, and at the same time providing us with a unique opportunity to come very close to the prehistoric or historic individual. Substantial information about past societies can be gained from the study of textiles, but this information depends on the analytical tools and methods used. A textile contains information about the process and the tools used in the various stage of its production. The decoding of a textile is imperative for the understanding of the many different processes involved in its production, and the methods may vary according to the state of preservation (Andersson Strand et al. 2010). For instance, the processing of a fiber material from the source to the final thread and the weaving and sewing will not only tell about breeding systems and the technological knowledge of that time but also indicate more subtle information about visual preferences and human desires.

Fiber identification is an important starting point in textile research as it indicates the properties of this material as well as the possible use. The identification of fibers is in most cases based on morphological characteristics performed by various types of microscopy. The optical microscopy is the most basic tool which together with scanning electron microscopy (SEM) enables precise photographing and measuring. In these cases sampling is necessary. Fiber identification can be difficult in cases of highly aged and deteriorated samples where fiber characteristics have been changed and/or where sampling is complicated by the fragility or the scarcity of the fibers. In such cases, scanning electron microscopy is especially useful and combined with energy dispersive X-ray spectroscopy (SEM/EDX) inorganic elements in the fibers such as pigments, mordants, and salts, and proteins in animal fibers can also be analyzed. Transmitted electron microscopy (TEM) can provide information on the internal fiber structure such as the pigmentation of wool fibers. Gas chromatography/mass spectrometry (GC/MS) and infrared microspectroscopy (FTIR) are useful analytical methods for the identification of resins, oils, and balsams that can have been applied to textiles. High-performance liquid chromatography (HPLC) is used to obtain information about dyes or dye components that are not visually detectable anymore. Especially, dye analysis provides important information to the archaeological interpretation that characterize visual preferences, technology, and exchange of know-how and goods (Vanden Berghe et al. 2009). Radiocarbon dating (^{14}C) can be used for textiles from disturbed contexts or contexts where no other datable object exists (Mannering et al. 2010). Textile materials are, in general, well suited and reliable for ^{14}C dating, although the presence of conservation substances should be evaluated before sampling. Stable isotopes can reveal facts about the nutrition (Wilson et al. 2001), while strontium isotopic analysis, which has now been adapted to fibrous material, can reveal whether the textiles are of local or nonlocal origin (Frei et al. 2008). DNA sequencing is useful for the identification of specific species, which are otherwise hard to identify, but the results highly depend on the preservation conditions (Ørsted Brandt et al. 2011). Detection of species of animal origin can also be done with mass spectrometry-based protein sequencing (MSPS) (Schmidt et al. 2011).

The constant improvement of scientific analytical methods and the development of new ones will often inspire further analyses. Yet, most analytical tools require sampling, and it is important to develop more nondestructive methods in order to secure our common world heritage, and to improve working conditions and the scientific outcome. The importance of taking samples should be evaluated prior to analysis, and sampling should preferably be done before any contamination has occurred. Accurate documentation, preferably

by photographs, of where samples have been taken is imperative.

Preservation and Conservation

The aim of an active conservation treatment is to improve the condition of the textile by trying to eliminate some of the causes of deterioration, and the aim of preventive conservation is to slow down the rate of further degradation (Skals 1996). Textiles preserved in archaeological contexts are often weak and tend to be fragile and decompose easily when exposed to changes in the climatic conditions and to touching and handling. A general rule is that dry textiles should be kept dry, wet textiles kept wet, and textiles should be stored in a cool place until the conservation treatment can commence. Adding consolidants during retrieval or biocides to avoid bacterial or fungus growth should be avoided as future scientific analyses thereby will be complicated or prevented (Gillis and Nosch 2007).

The method of drying waterlogged archaeological textiles and the questions of pretreatment with lubricating additives such as polyethylene glycol (PEG) or glycerol are factors which has been the focus of much discussion and research. Freeze drying has been evaluated as the gentlest form of drying. It can be done under vacuum or at atmospheric pressure. The discussions regarding pretreatment are somewhat unresolved because the additives in theory are soluble and the treatment reversible. Nevertheless, it can be very difficult to completely remove additives from archaeological fibers. Lubricants are often added to waterlogged wood to replace the water that has filled the empty spaces in the cell structure. Adding lubricants to textile fibers with the aim of replacing the water in the fiber structure is a different matter. The molecular structure is different from wood, and the empty spaces inside fibers are very tiny. Furthermore, the yarn structure, consisting of many fine fibers twisted together, will cause the liquid additives to run into all the air spaces and coat the fibers. Completely removing them is impossible without much damaging manipulation of the textiles. Also future scientific analyses will be unreliable. Avoiding the use of lubricants is therefore recommended (Peacock 2005).

Cleaning of textiles is an irreversible process, and the effect of cleaning on the condition of the textile must be evaluated before a treatment is chosen. Thorough cleaning of wet archaeological textiles prior to drying should be avoided as should also wet cleaning of dry archaeological textiles. Dirt can be the cause of long-term degradation but also be part of the history of the object. Likewise, the cleaning process may remove less stable substances like dyes and paint which may not be visible to the naked eye, or pollen assemblages stored in the textile, which in turn contain information about human activities and the environment.

The long-term preservation of textiles will be enhanced by good, clean, and cool storage. Fragile textiles should be supported, and shelves and drawers should be well fixed to eliminate mechanical damage. The textiles should be protected from deteriorating effects of light, heat, and high humidity, and regular monitoring for insect infestation is recommended.

Due to the fragile nature of textiles, they will inevitably degrade. Careful handling and ideal storage are preventive methods that can slow down the degradation, but they can never prohibit or stop it. Therefore, it is of utmost importance that archaeological textiles are analyzed and studied when possible. In this work, a useful tool is high-resolution digital photography which provides accurate documentation of the object and its condition at a certain time. At the same time, this technique also opens for a wider scientific use and dissemination of these fragile objects, which reaches beyond their physical presence.

Conclusion

Textile research is a worldwide occupation which is performed within many different disciplines. This is also the case within archaeological textile research where the theoretical and methodological approach, to a large extent, depends on the research traditions in the different geographical and cultural historical areas. Research in archaeological textiles are performed by, among others, archaeologist, historians, art historians, textile designers, conservators, and crafts people, and each in their way, they are able to contribute

with important aspects to the understanding of the production and use of textiles.

Textiles and fabrics are an important part of our common world heritage. Most cultures and peoples around the world use textiles for multiple purposes and the same are true for past societies. Common for this worldwide endeavor is first and foremost the wish to keep warm and comfortable, but textiles also have an important role in expressing who we are – our gender, age, family affiliation, status, occupation, religion, and ethnicity. Knowledge of textile history is hence a key to our understanding of a multitude of human issues.

Thailand: Cultural Heritage Management

Thanik Lertcharnrit
Department of Archaeology, Silpakorn University, Bangkok, Thailand

Introduction and Definition

Thailand has a long history of cultural development, but the management of cultural heritage under a protective framework did not begin until fairly recently.

It is interesting to note that throughout its history of cultural development, perceptions of the past varied from place to place depending upon influences such as religions, beliefs, and political situations. For example, Thai people as Buddhists generally perceive the past as something that represents change and becoming. It may be abandoned quickly and easily. It is expected that new things can be created, invented, or established. Thus, restoration or reconstruction of old pagodas or stupas, pavilions, and other religious buildings is not culturally wrong. Byrne (1995) brilliantly discussed the use of stupa and conservation conflicts in Thailand. Strictly speaking, the past as interpreted by King Rama VI, during his reign, was a key tool in building nationalism. He convinced the people to be proud of their culture and past (Vella 1978).

Historical Background

Regarding concern about the destruction of cultural heritage in terms of archaeological resource management in modern sense, the first protection law called "Pra Kaad Khet Rang Wat Poo Rai Khut Wat" or "Proclamation on Temple Boundary and Temple Looters" was issued in 1851 during the reign of King Rama IV (Fine Arts Department 1968). The main objective of the law was to prevent temples from being looted.

It should be noted that during his reign (1851–1868), Thailand (or Siam, as it was known at that time) was in an early stage of its development of international relations. While the king wanted to open the country to forge relationships with developed countries such as the United States, England, and France (see Symananda 1993), he was aware of the negative slide of colonization. For this reason, he revived an awareness of the past as a way of supporting nation building or developing a sense of national unity and pride (Symananda 1993).

Through his reign, a number of archaeological research projects, including the preparation of museum displays, were carried out. However, since the works were the result of the king's personal interests – not of government policies – they were conducted only by small groups of elites who worked only on royal projects. Nevertheless, the value and meaning of cultural resources were interpreted as important heritage of the nation, deserving protection.

The revival of the past was continued during the reign of King Rama V, (1868–1910). King Chulalongkorn, as he was also called, was not only a well-known reformer but also a great scholar. He was interested in a variety of disciplines such as archaeology, ethnography, and history; wrote a number of books concerning archaeology; set up a museum hall in his palace (1874); solicited the return of stolen objects from Museum of Ethnology in Berlin, Germany (1886); established the Museum Department (1888) which was a government agency; founded the Antiquity Club (1907), which promoted the study of archaeology, art, and history; and established the Literature Club (1914) (Fine Arts Department 1989; Charoenwongsa 1994; Ketudhat 1995). It should also be noted that the first scientific excavations that were conducted by Phraya Boranrajathanin in Ayutthaya were another important point that marks the progress in archaeological heritage management.

These greatly increased public awareness of the significance of cultural heritage and eventually led to the development of culture heritage management in the country. It should be stated that in the king's sense, cultural heritage referred to everything that was old. Thus, it is not surprising that, even at the present time, there is no clear and specific definition of cultural heritage used in the legislative context. The commonly used references are ancient monuments, ancient objects, and art objects.

In 1926, 6 years after the end of King Chulalongkorn's reign, the Bangkok Museum Act was enacted. This brought about the establishment of Thailand's first public museum, the Bangkok Museum. In addition, the regulations concerning "transportation of ancient objects and art objects" were promulgated in response to the immense trafficking and smuggling of antiquities. It should be noted that the management of cultural resources mainly involved the protection of archaeological remains.

A remarkable change occurred in the time of Prime Minister Field Marshal Pibulsonggram (1897–1964). Pibulsonggram clarified his role in the government, and tried to use elements of culture as tools to cultivate nationalism and patriotism. For example, he encouraged the people to use and buy only Thai products and required them to be in – what he called "civilized" – dressing, that is, coats, trousers, blouses, shirts, hats, gloves, and ties (Suwannathat-Pian 1995: 135–151).

Furthermore, Luang Wichitwathakan (1898–1962), a prominent scholar and prolific history writer in this period, asserted in one of his studies on the ethnic history of the Tai people that the Thais were the most ancient race, instead of "one of the most ancient" (Charoenwongsa 1994: 1). Kasetsiri (1979: 166–168) interpreted Luang Wichitwathakan's history as an ideological weapon of the new ruling elite, particularly the military, to seek justification for ruling the country.

During Pibulsonggram's government, a large number of acts, regulations, and laws that applied to cultural heritage were passed; the most effective ones were the National Culture Act of 1940, the 1940 Council of Culture, and the 1945 Act of the Ministry of Culture. In 1979, when General Kriangsak Chamananda was the Prime Minister, the Office of the National Culture Commission was established. Later, Prime Minister General Prem Tinsulanonda announced the national culture policy. Most recently, under the administration of Chuan Leekphai's cabinet, the government declared the year 1994 as the Thai Culture Promotion Year to promote public awareness of the value of Thai traditions and customs. This nationwide campaign dealt mostly with nonmaterial aspects of the culture such as beliefs, ideologies, religion, and folklore. In regard to the management of archaeological resources, the Fine Arts Department's Office of Archaeology, Ministry of Culture has taken responsibility since 1926.

Key Issues/Current Debates

The Administration of Cultural Heritage

The "official" management of cultural heritage in Thailand is a government duty operated by the two major departments of the Ministry of Culture: the Fine Arts Department and the Office of Cultural Promotion. The first organization is mainly responsible for tangible heritage preservation and management, particularly through the administration by the two offices of the Fine Arts Department, the Office of Archaeology and the Office National Museums, while the latter is largely taking care of intangible heritage. As for the tangible or physical cultural heritage, the Office of Archaeology is "the key agency working on the restoration of ancient monuments and archaeological sites. It is also responsible for the preservation and investigation of archaeological remains for the benefit of the nation, for the sake of the study of the nation's history, and for the perpetuation of the cultural heritage of the nation" (Fine Arts Department 1990: 24).

Administratively, the Office of Archaeology is one of the ten agencies of the Fine Arts Department in the Ministry of Culture, which is the only organization responsible for the management of cultural resources in the country. The Office of Archaeology was first formed as a club in 1908 – the Antiquity Club. It was gradually reformed and

its status was later changed from a private club to a government agency. In its administrative structure, the Office of Archaeology is divided into seven sections: General Affairs, Planning and Evaluation, Research, Restoration and Preservation of Ancient Monuments, Preservation and Restoration of Mural Painting and Nonremovable Sculptures, Control and Maintenance, and Historical Park Projects.

Furthermore, according to the law, the Office of Archaeology is given full authority to grant permission or reject proposals for undertaking archaeological investigations on public land. In 1995, the Office of Archaeology was merged with the Office of National Museums into the Office of Archaeology and National Museums but was later separated as an individual agency under the umbrella of the Fine Arts Department as is the Office of National Museums.

Broadly speaking, there are two major groups of archaeologists in Thailand. One group, whose work is mostly concentrated on restoration, preservation, and inventory of archaeological sites, districts, and ancient cities, is associated with the Fine Arts Department (FAD), while the other is associated with academic institutions such as universities and colleges. In response to the Historical Park Projects, a great number of surveys of archaeological sites and monuments by FAD's archaeologists during the past ten years were primarily and specifically designed to rescue major archaeological sites and then develop them into "historical parks." Charoenwongsa (1994: 2) remark: "administrators/managers enjoy themselves more towards restoration of ancient monuments. The situation has not changed very much. . . ." This seems ironical because Musigakama (1995: 38), a former director of the Office of Archaeology, stated that the Office of Archaeology is responsible not only for survey, maintenance, restoration, and preservation of archaeological heritage but also for scientific study of archaeological records.

After joint expedition projects with foreign counterparts during the 1960s, the Thailand's Fine Arts Department initiated many mobile projects to counter looting activities in the 1970s. Under the direction of Pisit Charoenwongsa, the Northeast Thailand Archaeological Project was established in 1975 out of its predecessor, the Ban Chiang Excavation Project (a joint effort between the Fine Arts Department and the University Museum, University of Pennsylvania which was carried out under the coordination of Pisit Charoenwongsa and the late Dr. Chester F. Gorman). With the success of the Northeast Thailand Archaeological Project, the Office of Archaeology (then called as Archaeology Division) created another three regional – northern, central, and southern Thailand – archaeological projects.

Following that, regional field projects were brought under the central administration of Thailand Archaeological Project (TAP). As director of TAP and the Research Section of Archaeology Division, Pisit advised his younger colleagues to choose among themselves their own project directions. In 1980s, Khemchart Thepchai, Tarapong Srisuchart (current director of the Office of Archaeology as of 2012–2013), Bovornvate Rungruchee, Amphan Kijngam, Sathaporn Khanyuen, Sayan Pricharnchit, and Niti Saengwan were directors of these regional projects. To enrich their experiences, some of them moved or rotated from one project to another.

In the 1980s, the Thailand Archaeological Projects and its regional field projects produced several hundred site survey reports for the first time and with that came a large data collection which resulted in about 50 publications in book form during the late 1980s and beginning of 1990s.

There are both pros and cons in the cooperation between western and Thai archaeologists. Many good elements brought by western colleagues include the concept of multidiscipline/problem-oriented research programs and systematic study of archaeological remains. However, some projects caused misunderstandings and negative feelings between participants, due largely to differences in culture/traditions and the self-centeredness of certain individuals.

Legislation Relating to the Protection of Cultural Heritage

As mentioned earlier, the first protection law issued in the reign of King Rama IV was short lived and was limited to the protection of royal temples. In 1934, the first comprehensive legislation was drafted and was later amended three times – in 1943, 1961, and 1992. The last amendment was announced in the Royal Gazette on March 29, 1992 in the reign of the present king. This has been called Ancient Monuments, Ancient Objects, Art Objects and National Museum Act of 1961. In addition, a number of separate regulations such as the Act of the Ministry of Education and the Announcement of the Fine Arts Department have been occasionally issued in line with the Act of 1961 (for details, see Fine Arts Department 2005).

The 1961 Act, together with additional amendments and regulations, has broad coverage: it includes definitions of specific terms, regulations, permit applications, ownership, lists of endangered sites, national museum, and illegal trafficking, transportation of ancient objects, and penalties.

Unlike such other countries as the United States and Australia, Thailand has no particular law on burial sites, underwater archaeological sites, and properties belonging to particular ethnic or indigenous peoples. According to the act, any objects buried or left on public land belong to the nation.

Public Education

Public interest in cultural heritage is powerful, as the public becomes the driving force behind efforts to conserve the past. In Thailand, the first formal center for public education in archaeology is the Faculty of Archaeology, Silpakorn University. This institution has the only center of training and recruitment of archaeologists for over a decade. Most Thai archaeologists have been trained at this institution. The courses focus mainly on Thai archaeology and a basic understanding of archaeological practices, and the degrees offered are B.A., M.A., and Ph.D. It was as recent as just in 2006 that an undergraduate course entitled "Cultural Resource Management" was included and taught for the first time in Thailand by the faculty members and experts from other government and private organization throughout the country at Silpakorn University Department of Archaeology. An M.A. program in Cultural Resource Management at Silpakorn University has been offered since 2007, and it has been well received, judging by the increasing number of students.

Interestingly, during the past few decades, many other public schools, colleges, and universities, for example, Thammasat University, Chulalongkorn University, Khon Kaen University, Chiang Mai University, Srinakharinwirot University, Burapha University, and several other colleges (mostly former teachers' colleges which are now known as Rajabhat University Complexes), have developed archaeology programs and have introduced archaeology courses in their curriculum, but none offers degrees in archaeology. Archaeology programs have yet to be introduced to the elementary and secondary schools. Therefore, school children learn very little about Thai history and culture in schools.

Besides formal education, knowledge about the past has been transmitted to the public through various kinds of nonformal educational mediums. Museums are one type of nonformal education centers; throughout the country, there are more than 30 public museums operated by the Office of Archaeology and National Museum. In 1995, for example, the Thai government granted a budget of about 2 billion baht (about $80 million) to build provincial museums throughout the country.

In addition to the government-owned museums, there are a number of private museums and public organizations such as the Museum of the Siam Society, the Ancient City Co. Ltd, the Jim Thompson House, Princess Maha Chakri Sirindhorn Anthropology Centre, Museum Siam, and the Museum of Prehistory in Siriraj Hospital of Mahidol University. There are also groups of archaeological volunteers who occasionally organize field trips to archaeological and historic sites

around Thailand, as well as neighboring countries such as Laos, Burma, Cambodia, and Vietnam. It is an indication that archaeological study tours are now becoming popular in Thailand. It should also be noted that during the past 5 years, there has been an increase in numbers of public magazines promoting natural and cultural tourism in Thailand and neighboring countries.

Major Contemporary Problems

Major problems concerning the management of archaeological heritage in Thailand are basically similar to those found in other countries in the world.

Looting

Looting is probably a never ending problem in Thailand. Through time, many archaeological prehistoric and historic sites have been illegally unearthed. In many cases, the looters are asked by middlemen who are merchants from Bangkok to hunt for antiquities. The ideal sites for looting are prehistoric sites in central and northeastern Thailand where they can easily gain access and where the sites cover large areas. The artifacts hunted in clued pottery, stone bracelets, beads, and bronze weapons. Surprisingly, a man in a team of looters confessed, when arrested, that he learned how to dig by observing archaeologists while they were at work. Another woman in the same team said that they have no choice but to hunt for antiquities for money because they were poor and did not own any pieces of land (Pumathon 1994: 28). In the case of historic sites, the favored artifact classes would be Buddha images and architectural decorative elements (e.g., stone lintels, wooden windows, and doors of Buddhist monasteries).

Government Officials Versus Local People

This problem arises mostly in the context of restoration of monuments which are currently used as shrines or sacred sites. This may be due to different understanding of the value of archaeological resources between government officials and local people. For example, most recently, there was a movement of people in Lopburi Province to protest the restoration of an ancient monument in the city. Archaeologists from the Office of Archaeology wanted to dissemble the monument and restore it by the so-called "anastylosis" method, but the people in the province wanted to know why the monument had to be taken apart first. They were very concerned about the destruction of the monument because it has great spiritual value for the people in the province.

In another case, the Office of Archaeology reshaped a giant pagoda, Wat Chedi Luang, in Chiang Mai, northern Thailand, without enough investigation and public hearings. The restoration resulted in the deformation of a pagoda which disappointed the locals and the scholars so much that they called a meeting to stop the work (Suksawasdi 1993).

There are few well-trained archaeologists working in government agencies, most of them received only basic training and have limited experience in doing archaeology. They often face problems because, many times, they are assigned to carry out work for which they are not trained.

Problem of Contract Work

At present, the preservation and restoration of archaeological remains and historic buildings is in the hands of technicians, rather than archaeologists. Archaeologists should research essential informational before the restoration begins, as a practical and academic approach, but often that task is left to the technicians. Probably due to the lack of sufficient evidence, a clear explanation of why this problem still remains is impossible. It is strongly recommended that a code of ethics of practitioners must be prepared. These technicians are lacking in basic archaeological knowledge, and they are even lacking in appreciation for the value of cultural resources. They just want to finish their work as soon as possible because of constraints of time and money. Thus, a lot of valuable information has been lost. For example, in the restoration of an ancient ruin in Ratchaburi, workers of a contract company reconstructed the ruin by first disassembling it and then reconstructing it. Unfortunately, the workers did not know what the original shape of the monument had been. The result of their work is archaeologically wrong, and the monument looks very ugly.

Different Perception of the Value of Cultural Heritage

Conflicts between cultural heritage practitioners and the local people have occurred due to different understanding of the value of cultural resources. Archaeologists of the Office of Archaeology and cultural heritage practitioners tend to focus on the informational and economic value of the archaeological resources, while the local people consider their spiritual or symbolic value. A good example is a small simple hillock near a temple in a village of Nakhon Phanom Province. Outsiders may view it as just a normal natural setting in the area, but for people in the village, it is a "sacred place" according to their myth. Annually, the villagers perform religious rites and celebrations at the place which has also been an important meeting area between people from Laos and Thailand (Vallibhotama 1992: 211). My recent pilot research (Lertcharnrit and Niyomsap 2008), conducted in a remote village where archaeological site museum is located in central Thailand, on indigenous perceptions and knowledge about archaeology revealed that when asked what archaeology is, the majority of respondents (41%) perceived that archaeology is human skeletal remains (see Table 1).

Thailand: Cultural Heritage Management, Table 1 Public knowledge and perception about archaeology in a Thai village in central Thailand when asked "what do you think of when you hear the word "archaeology?" (N = 85)

Archaeology in villagers' perceptions	Percentage of answers
Human skeletal remains	41.18
Artifacts	23.53
Ancient history/the past	17.65
Ceramics/ancient ornaments (beads, bracelets)	14.12
Ban Chiang[a]	9.41
Ban Pong Manao[b]	2.35

[a]Ban Chiang is a widely known prehistoric site in the northeast because it is a cultural world heritage site
[b]Ban Pong Manao is an Iron Age site where an archaeological site museum is located and also the name of the village I conducted the research

Future Directions

The "professional" management of cultural heritage in Thailand has long been developed, and it is still in need of further development. It needs a lot of change especially in term of legislation and policy. To reduce controversy, the protection law should be open for public participation, providing opportunity for the public to offer input into decisions and actions.

Cooperation between the Fine Arts Department and other private and government agencies/organizations and public audiences, on both local and national levels (i.e., the Ministry of Agriculture, Ministry of Education, Department of Highways, Department of Religious Affairs, Royal Irrigation Department, Amateur Cultural Heritage Conservation Clubs, Subdistrict Administration Organizations, village heads, provincial governors, etc.), will help upgrade the quality of the management program.

The Fine Arts Department's Office of Archaeology desperately needs to build nationwide and worldwide networks in the coming years, while a strong public education program should be considered as part of an essential strategy to change public attitudes toward the past.

It should be remembered that the people who live near the sites are the best protectors of cultural resources. Once people have recognized the value and meaning of cultural resources, protection and management will be more successful.

Lastly, in the globalization era, the Fine Arts Department's Office of Archaeology should also build global alliance with international organizations and professionals, not only the UNESCO and ICOMOS which Thailand is a member but also other nonprofit organizations located in southeast Asian countries, such as the Heritage Watch in Cambodia, and in broader regions of the world (e.g., the Getty Foundation, the World Archaeological Congress, the Southeast archaeological Center). In addition, local and public participation and cultural education programs must be developed as well.

Theoretical Archaeology Group (TAG)

Zoe Crossland[1] and Andrew Fleming[2]
[1]Department of Anthropology, Columbia University in the City of New York, New York, NY, USA
[2]The School of Archaeology, History and Anthropology, University of Wales, Trinity Saint David Lampeter, Ceredigion, Wales, UK

Brief Definition of the Topic

A conference that is known as much for its social life as its cutting-edge theory, the Theoretical Archaeology Group (TAG), is a successful and idiosyncratic institution in the prime of life. The organization has a distinctive and somewhat anarchic ethos, consisting of an annual conference that meets once a year, with no membership requirements or dues. The meeting moves from one university to another annually (the Republic of Ireland is included) and is organized by volunteers from the host institution. Efforts are made to keep costs down for each meeting and to provide cheap or free accommodation for students, so that the conference is affordable and available to all. Each conference is run entirely by the sponsoring institution, so that each one differs according to the priorities and interests of the department that hosts it. Representatives of institutions that have previously hosted TAG gather for an informal committee meeting at the annual conference. This committee hears pitches and makes decisions as to where the conference will next be held. In the UK TAG is now in its fourth decade of meetings, with attendances generally in the range of 400–600 participants, including some from overseas. TAG has produced healthy offspring, including Nordic TAG, held biennially in Scandinavia, and TAG-USA, which began in 2008 at Columbia University. Other conferences that have been influenced by the TAG model include the Theoretical Roman Archaeology Conference (TRAC) and, most recently, STAG, the Scottish Theoretical Archaeology Group and

TAG Turkey, held at Ege University, Ä°zmir in May 2013. In this entry we will provide a brief overview of TAG's history and development in the UK and the USA.

TAG emerged at the end of the 1970s, in a search for a British venue to discuss archaeological theory. A conversation between Colin Renfrew, then at Southampton University, and Andrew Fleming at Sheffield led to the formation of a Sheffield-Southampton colloquium. Its third meeting, held in Sheffield in 1979, was open to all, and from 1981, when it was hosted by Reading University, the conference started its current pattern of being held at a different sponsoring university every year (a more detailed history may be found in Fleming and Johnson 1990). TAG has developed into a venue where a postgraduate student can give his or her first academic paper and also mingle with established academics on the dance floor or in the conference room. The conference aims to open a productive space for dialog, with the emphasis on the theoretical and political implications of a topic. Sessions are kept open to encourage participation and to foster a diverse range of perspectives. Since the late 1980s the conference has been something of a nursery for post-processual and interpretive archaeologies (e.g., Bintliff 1991 and response by Thomas and Tilley 1992). It is sometimes said that TAG participants can become obsessed with the quest for new theoretical perspectives (Chippindale 1990: 464), but then again, TAG is a great place to get a sense of the questions that are animating the field at any particular moment; its agenda is driven by its participants. The British meeting has seen less intense debate in recent years, perhaps because of the growth in the number and size of sessions. Experimentation is not restricted to the topics of papers; in recent years participants have tried out a variety of formats and venues for their contributions. Memorable sessions include the video installation "Neolithic Stories Untold" at the 2003 conference at the University of Wales Lampeter (van Rossenberg 2004: 56), a poetry poster session on landscape and archaeology at Sheffield TAG in 2005, and an "intervention" organized by Ian Russell and Andrew Cochrane at York TAG in 2007. This included the placement of 150 replica Cycladic figurines around the conference buildings and grounds (http://www.iarchitectures.com/irac2.html#show). Reactions varied from enthusiastic collection of the objects to nonplussed indifference.

The US TAG was started in 2008 at Columbia University, where it was imported by two British archaeologists Brian Boyd and Zoë Crossland. Although the US TAG was modeled on the British conference in terms of ethos and organization, it has gone on to develop its own character and theoretical interests. British TAG has a strong core focus on British and European prehistory, whereas the US conference deals with a more eclectic range of regions and time periods and is quite interdisciplinary in feel. Sociocultural anthropologists, geographers, philosophers, historians, and social theorists are regularly included in sessions, whether as discussants or presenters. TAG-USA also has a substantial proportion of international participants, with around 40% coming from outside the USA at the first conference at Columbia University. Severin Fowles' Thing Theory session from the same conference gives a sense of the feel of TAG in the USA. This session included participants from the USA, Canada, Europe, and South America and counted students and established scholars among the people involved. Participants came from a range of backgrounds, including contributions from outside archaeology, such as those by Jane Bennett and Brian Larkin. The session also had an associated art exhibit entitled "nomadic dresses," a project by Mariana Frochtengarten that used the circulation and modification of clothing between artists to explore the role of material culture in social interactions and exchange.

Links to all the conference websites (some no longer in operation unfortunately) can be found on Antiquity's website (http://www.antiquity.ac.uk/tag/index.html), which also lists publications arising from the conference, as well as articles about TAG, many of which are affectionate and critical reviews of particular annual meetings. There is also a US website that provides links and information about TAG in the USA (http://www.tag-usa.org). Pamela Jane Smith has started to record and archive the oral history of TAG, carrying out interviews with archaeologists who were involved in its early days (http://www.arch.cam.ac.uk/

personal-histories/tag.html), and recently archaeologists have started to study the history of the conference itself as a means to track the changing profile of archaeology over the years (Gaydarska 2009).

Thomas, Julian

Thomas H. Bowden
College of Humanities, Arts and Social Sciences, Flinders University, Adelaide, SA, Australia

Basic Biographical Information

Professor Julian Stewart Thomas, born 1959, is a British archaeologist who specializes in the archaeology of Neolithic Britain as well as archaeological philosophy and theory, particularly in regard to modernity (Thomas 2004), postprocessualism (Thomas 1996) and archaeological theory (Thomas 2015). He undertook a Bachelor of Technology in Archaeological Sciences at Bradford University from 1977 to 1981. Later, at Sheffield University, he completed his Masters of Arts in Environmental Archaeology and Palaeoleconomy from 1981 until 1982, and then a PhD in Archaeology which he completed in 1986. Between 1987 and 2000, he held a variety of lecturing positions in archaeology at the University of Wales, Lampeter, and at Southampton University. He is currently a Professor of Archaeology at Manchester University.

Major Accomplishments

Julian Thomas has many accomplishments in terms of significant publications and the development of archaeological theory, as well as important and noteworthy fieldwork.

Thomas is well-known for his work on Neolithic Britain, publishing several major works on the subject such as the book *Rethinking the Neolithic* (Thomas 1991) and the follow-up, *Understanding the Neolithic* (Thomas 1999), as well a series of papers on the subject. He has discussed the "Neolithic" as a concept in his major works and in journal articles on Neolithic burial practices, landscapes, and approaches to landscape, housing, societal organization, rituals and religions, and more.

Another field of Thomas' expertise is archaeological philosophy and theory, with several papers by him appearing on subjects as diverse as the future of archaeology theory and practice, the apparent trend towards a "death of theory," and archaeology's place in the modern world. Other topics that Thomas has discussed include issues associated with a "materialist" approach to contemporary archaeology, phenomenology and material culture, the hermeneutics of "megalithic space," archaeological humanism, and megalithic art design. He is classed by Trigger (2006: 470, 472) as a post-processual archaeologist with a humanist approach, along with others from the so-called "Third Wave" of post-processual interpretation,

such as Christopher Tilley, John Barret, Christopher Gosden, and Cornelius Holtorf.

Julian Thomas has directed ten archaeological field projects since 1989 at places such as Banc Rhosgoch Fach, Pict's Knowe, Holywood, Holm Farm, and Dunragit. He has co-directed 22 field projects since 1983 at places that include Avebury, Anglesey, Durrington Walls, and Dorstone Hill.

One of Thomas' recent projects is the Dorstone Hill Neolithic Landscape. He has been excavating as part of this project since 2011 in southwest Herefordshire. Another key project is the Stonehenge Riverside Project, undertaken between 2004 and 2009 with Mike Parker Pearson and Chris Tilley.

At the time of writing, Thomas has written nine published books either as primary author or with collaborators and has two additional books in press. He has been the co-editor of 11 books on topics that include the European Neolithic, interpretive archaeology, and landscape archaeology. Since 1984, Thomas has authored or co-authored 68 academic journal articles and 81 book chapters. In 1999, with Prof. R. Layton, he authored a report to the Executive of the World Archaeological Congress on *Proposals for a tunnel at Stonehenge: an assessment of the alternatives*. In 2015, together with R. Van Dyke, S. Lekson, and C. Heitman, Thomas authored an official report to the US National Parks Department entitled *Chaco Landscapes: Data, Theory and Management.*

Thomas has been on the editorial board of a number of journals including the *Journal of the Royal Anthropological Institute* (1992–2004), the *Journal of Material Culture* (1995–present), *Time and Mind* (2005–present), the *Journal of Social Archaeology* (2010–present), and *Current Swedish Archaeology* (2011–present).

During his career, Julian Thomas has served on many national and international archaeology and anthropology bodies. From 1994 to 1999, he played a major role in the democratization of archaeology globally in his role as Secretary of the World Archaeological Congress. He has also made major contributions to archaeology as Vice Chair of the United Kingdom Subject Committee for Archaeology and as Vice President of the Royal Anthropological Institute from 2007 to 2010. Since 2017, Thomas has been on the Finance Committee of the Royal Anthropological Institute, and since 2018, he has been a Member of Council and on the Honours and Awards Committee for the same.

The excellence of Julian Thomas' work has been recognized in a several high prestige awards. These include the Arts and Humanities Research Board (AHRB) Research Leave Award in 2003, the 1999 Curl Lectureship of the Royal Anthropological Institute, and the 1995 Bob Smith Award from the Prehistoric Society. At the University of Manchester, he was nominated for the 2015–2016 "Best Supervision (Postgraduate Research)" and for the 2014–2015 "Most Inspiring Lecturer" and "Best Humanities Lecturer."

Julian Thomas is an outstanding researcher and committed teacher. Though still young, he has had a major impact on archaeology in Britain and globally (Figs. 1, 2, and 3).

Thompson, Homer

Daniel P. Diffendale
Interdepartmental Program in Classical Art and Archaeology, University of Michigan, Ann Arbor, MI, USA

Basic Biographical Information

Homer Thompson (1906–2000) is best known for his formative contribution to the excavation of the civic center of ancient Athens. He was born in Ontario and raised in British Columbia, the son of classically minded parents. He received his B.A. and M.A. in Classics from the University of British Columbia, Vancouver, in 1925 and 1927, respectively, and his Ph.D. from the University of Michigan in 1929. That same year he collaborated

with the Greek archaeologist Konstantinos Kourouniotes on an investigation of the Athenian Pnyx. On the recommendation of Benjamin Dean Meritt, Thompson was appointed one of the first two fellows of the American School of Classical Studies at Athens' excavations in the Athenian Agora, in 1931. At the Agora he met and married another fellow, Dorothy Burr, a prominent archaeologist in her own right.

Major Accomplishments

From 1933 to 1947 Thompson held the position of Professor of Classical Archaeology at the University of Toronto, concurrently acting as an assistant curator of the classical collection at the Royal Ontario Museum. This term was interrupted by World War II, during which Thompson served as an intelligence officer with the Royal Navy, stationed at Bari. Visiting Athens in 1944, during the Greek Civil War, he was briefly held captive, but talked his way out and parted from his captors on friendly terms. He was appointed field director of the Agora Excavations in 1945, a position he held until 1967. In 1947 Thompson became Professor of Classical Archaeology at the Institute for Advanced Study in Princeton, a position he retained for over 50 years – as emeritus from 1977 onward – until his death in 2000. He received the Archaeological Institute of America's Gold Medal for Distinguished Archaeological Achievement in 1972.

Thompson devoted his career to the study of the Athenian Agora and played a tremendous part in the formation of its current physical and intellectual state. He authored numerous scholarly articles as well as two monographs, including 1972's *The Agora of Athens* (with R. E. Wycherley). He supervised the publication of the first 11 volumes of the Agora excavation series, as well as a series of Agora Picture Books, designed to be easily accessible to a general audience. Thompson was insistent that archaeologists had a responsibility to the public to present and publish the results of their work. Above and beyond his own publications, Thompson's great accomplishment was in bringing together and overseeing a large and diverse group of scholars for over 20 years.

Thomsen, Christian Jürgensen

Poul-Otto Nielsen
The National Museum, Copenhagen, Denmark

Basic Biographical Information

Christian Jürgensen Thomsen (1788–1865) organized the major Danish museum collections in the mid-nineteenth century and became famous for introducing the Three-Age System, the division

Thomsen, Christian Jürgensen, Fig. 1 C.J. Thomsen (1788–1865). (Painting by J.V. Gertner. The Danish National Museum)

of prehistoric time in a Stone, Bronze, and Iron Age (Fig. 1). He was born in Copenhagen as son of a wealthy merchant, whose business he carried on after the death of his father in 1833. As a young man, he developed an excellent knowledge of numismatics, history, and art, and he made personal acquaintance with many of the young artists of that time. In spite of having no academic background, in 1816, he became secretary of the Royal Commission for the Preservation of Antiquities, established in 1807, obtaining official membership of the Commission in 1827. Besides being responsible for the Museum for Nordic Antiquities (Fig. 2), Thomsen became the organizer of other museum collections in the 1840s and 1950s. From 1830, he was a member of a commission organizing the Royal Armory Collection. In 1832, he was attached to the Coin Cabinet as inspector and became its director in 1842. From 1839, he also worked as an inspector at the Royal Museum of Art. For his extraordinary efforts to organize the most important Danish museums, he obtained the order of high-ranking councilor. He was succeeded as director for the Museum for Nordic Antiquities by J.J.A. Worsaae.

Thomsen, Christian Jürgensen, Fig. 2 C.J. Thomsen showing the Museum for Nordic Antiquities to visitors at the Christiansborg Castle in 1846. (Drawing by Magnus Petersen. The Danish National Museum)

Major Accomplishments

As secretary of the Antiquities Commission, Thomsen started to catalogue the collection of the Museum for Nordic Antiquities, the embryo of the later National Museum, in 1817. In 1819, he arranged an exhibition of antiquities in a limited space adjacent to the University Library on the upper floor of the Holy Trinity Church in Copenhagen. It was during recording and arranging the collection that Thomsen developed the Three-Age System, not only as a technological model but as a chronological sequence based on the combination of finds (Gräslund 1981). He emphasized the importance of careful recording of find circumstances during archaeological excavations and thereby introduced a principle fundamental to archaeological practice. In 1825, Thomsen had worked out a definition of the Stone, Bronze, and Iron Ages, which was initially disseminated through his correspondence with learned colleagues. One of them was Bror Emil Hildebrand

(1806–1884) at the Historical Museum of the University of Lund, Sweden, who visited Thomsen in 1830 and subsequently arranged the collection of the Historical Museum in Lund according to the Three-Age System (Stjernquist 2005). In 1833, the Museum for Nordic Antiquities had been moved to new premises at the Christiansborg Castle in Copenhagen, where Thomsen could arrange the prehistoric and medieval collections under more favorable conditions and where the Three-Age System came to justice. Thomsen's own description of the Three Ages was not published before 1836 in his contribution to *Ledetraad til nordisk Oldkyndighed*, which was translated into German (1837) and English (1848) and thereby obtained international attention. Thomsen's own literary production was limited, but his work can be followed in his correspondence with colleagues. In 1856–1857, he issued a publication about Nordic gold bracteates with a classification that laid the foundation for later research.

Thomsen became responsible for establishing other museum collections, when the Royal Danish *Kunstkammer* was broken up in the 1840s (Gundestrup 1985): the Ethnographical Museum in 1841 (Hermansen 1941), the Classical Antiquities Cabinet in 1851, and the Museum of Sculpture and Handicraft in 1852. Under Thomsen's leadership, these collections, the Museum for Nordic Antiquities and the Coin Cabinet, were brought together during the 1850s and 1860s under one roof in *Prinsens Palais*, since 1892 the permanent residence of the National Museum. Thomsen was also actively engaged in the establishment of local museums in major provincial towns such as Odense (in 1818), Kiel (in 1834), and Flensburg (in 1852).

Of Thomsen's own collection of coins, the largest in private ownership at that time, more than 12,000 medieval coins were purchased by benefactors after his death and donated to the Coin Cabinet.

T

Throckmorton, Peter

George F. Bass
Texas A&M University, College Station, TX, USA

Basic Biographical Information

Peter Throckmorton (1928–1990) played an enormous role in the creation of the field of nautical

archaeology. Born in New York, he eventually rebelled against his privileged background, running away from boarding school in Colorado to seek adventure. He worked on various vessels in the Pacific, finally reaching Hawaii, where he learned to dive. After four years in the army, in Japan and Korea, he enrolled in the University of Hawaii and worked on a terrestrial archaeological excavation. Although he never graduated from college, he also studied at the Musée de l'Homme in Paris.

Major Accomplishments

Working as photojournalists, Throckmorton and Herb Greer covered the Algerian War dressed as rebels. In 1958, on returning overland to Europe from shooting a tiger-hunt story in India, he stopped in Bodrum, Turkey, to write about local sponge divers. Sailing and diving with Kemal Aras, he was shown ancient wrecks and was told about the most intriguing, which lay near Cape Gelidonya on the southern coast. He reached that site the following year while guiding an American sailing expedition. Recognizing that the wreck dated to the Bronze Age, he convinced the University of Pennsylvania Museum to organize an expedition, which led in 1960 to Throckmorton and George Bass conducting the first complete excavation of an ancient shipwreck on the seabed.

Throckmorton then moved to Greece where, beginning in 1962, he mapped the remains of two Roman stone carriers near Methone. He sailed his *Archangel* to Italy to explore other Roman stone carriers and, in 1967–1968, with his wife Joan, excavated one at Torre Sgaratta that carried sarcophagi from the late second or early third century. By then he and Gerhard Kapitän had excavated a seventh-century hull partly preserved in a marsh at Pantano Longarini in Sicily.

Back in Greece in 1970, he recognized that an old motor ship was a converted square rigger and determined that she was the *Elissa*, built in Liverpool in 1877; he and Karl Kortum of the San Francisco Maritime Museum acquired the vessel and arranged for her to be purchased in 1975 and restored by the Galveston Historical Foundation; she is now a major tourist attraction and sail-training ship in Galveston, one of her original ports of call. Also in 1970 he partially excavated a cargo containing twelfth-century Byzantine plates at Pelagos in the Northern Sporades and in 1975 located another Bronze Age wreck (2500 BCE) at Dokos near Hydra.

He recognized the importance of the many nineteenth-century hulks preserved in the Falkland Islands and in 1976 explored and surveyed the clipper ship *Snow Squall* (1851), the *Charles Cooper* (1856), and the Maine-built *St. Mary* (1890), a section of which he sent to the Maine State Museum in 1978.

From 1986 to 1988, Throckmorton was an adjunct professor at Nova Southeastern University. He died at his last home, in Newcastle, Maine.

His books include *The Lost Ships* (1964), the misleadingly titled *Diving for Treasure* (1965), *Shipwrecks and Archaeology* (1970), *The Sea Remembers: Shipwrecks and Archaeology* (1987), and *Spiro and the Sponge Fleet* (1964) for children.

Tibetan Plateau, Archaeology of

Anke Hein
School of Archaeology, University of Oxford, Oxford, Oxfordshire, UK

Introduction

Considering the relatively short history of archaeological research on the Tibetan Plateau, this field is remarkably contested. Major problems that vex the field are a lack of reliable dates, the dearth of archaeological material, the unevenness of research in various parts of the Plateau, and political issues. Nevertheless, recent multi-method research involving archaeology, genetics, linguistics, paleobotany, zooarchaeology, and isotope studies has thrown new light on the question of the early peopling of the Tibetan Plateau, human adaptations to local environment(s), and connections between the Plateau and surrounding regions.

Definition and Background

The term "Tibetan Plateau" (also Qinghai-Tibet Plateau or Himalayan Plateau) refers to a geographic unit rather than the political entity of the Tibetan Autonomous Region (referred to as "Tibet" in the following) or Greater Tibet as claimed by Tibetan exile groups. The Tibetan Plateau encompasses parts of northern India (Ladakh, Lahaul and Spiti, northern Sikkim, parts of Arunachal Pradesh), northeast Kashmir, Bhutan, northern Nepal, and parts of western China (Tibet, Qinghai, parts of western Gansu, eastern Sichuan, Northwest Yunnan). The southern border is formed by the inner Himalayan range; the Kunlun Mountains provide the northern limits beyond which lie the Hexi Corridor, the main contact route from China to the West; the East is described by the forested ridges of the foothills of the Qilian and Hengduan Mountain Ranges, and the western border is the Kashmiri Karakoram range.

The Tibetan Plateau is an elevated plateau covering an area of about 2,500,000 km^2 and has an average elevation of over 4,500 masl. The headwaters of most streams in the surrounding areas originate in this plateau, and it is also rich in glaciers. Over the millennia, it has been subject to desertification and other changes, making it an important study ground for the impact of climate change. The local environment is highly varied, including deserts, steppes, forests, salt lakes, mountains of up to over 7,000 m in elevation, and a wide range of plant and animal species. The climate in the center of the Plateau is arid, the southern and eastern margins are characterized by grasslands, and on the edges forests abound. There is strong seasonal variability, and climate changes have affected the region greatly, but the Plateau itself has also shaped global climate patterns due to its extreme height, influencing especially monsoonal patterns and the jet stream (Lehmkuhl and Haselein 2000).

Around 50,000 BP, the climate was colder and more arid than today and vegetation was sparse. Between 50,000 and 25,000 BP, temperatures increased, lake levels rose, and the climate became less dry, leading to steppe formation and greater species diversity. Conditions deteriorated during the Last Glacial Maximum (22,000–18,000 BP), starting a process of desiccation that continued into the Holocene (15,000–9,000 BP). Developments varied regionally, the east and south becoming warmer and more humid, leading to forest growths 13,000–10,000 BP. The western part became wetter and warmer only in 10,000–9,500 BP, with another arid period until 3,000 BP with two wet interludes (9,500–8,700 BP, 7,200–6,300 BP). From 6,000 BP, forests were greatly reduced, be it due to diminished rainfalls and lower temperatures, especially from 3,000 BP, or the expansion of agriculture or both (Miehe 1996). Due to the inhospitable conditions, today and probably in the past, the utmost West of the Plateau belongs

to the least populated regions of the world. Overall, the Plateau is characterized by much variability and great extremes, leading to varied human responses and thus much variability in the archaeological record over space and time.

Historical Background

The Tibetan Plateau is difficult to work in, not just because of the challenging environment and variety of languages involved but also for political reasons. The Plateau is unevenly split between different countries (mostly China, India, Nepal, Bhutan), and some areas are under dispute, most importantly Arunachal Pradesh, Kashmir, and to a certain extent Tibet.

Nevertheless, the extreme conditions and breathtaking scenery of the Plateau have attracted adventurers and scientists for centuries. Western explorers of the 1930s and 1940s remarked upon the presence of archaeological sites in various parts of Tibet. Prior to the 1980s, research in Tibet focused on environmental studies and geology. Nevertheless, related surveys of the 1960s and 1970s recorded some archaeological sites as well. While the national archaeological surveys of 1956 and 1981 covered all other Chinese provinces, it was only in 1984–1992 that a systematic survey of Tibet was conducted. The results appeared in 2010 in the series *Atlas of Chinese Cultural Relics* 中国文物地图集 (Guojia 2010), recording more Buddhist temples and historical buildings than prehistoric or early historic settlements or grave sites. The most recent Nationwide Cultural Relics Survey 第三次全国文物普查 included Tibet and leads to the discovery of many new sites, but the results are as yet unpublished.

Archaeology in Tibet is administered by the Tibetan Bureau of Cultural Relics 西藏自治区文物局 and since 1999 also facilitated by the Tibet Museum in Lhasa, but field research is largely conducted by other institutions, such as the Academy of Social Sciences 社会科学院, Sichuan University which has a designated Center for Tibetan Studies 四川大学中国藏学研究所, Peking University, and individual researchers from other institutions, always in cooperation with the Tibetan units themselves.

The exploration of prehistoric monuments in India started in the nineteenth century, officially with the establishment in 1861 of the Archaeological Survey of India (ASI), which exists until the present day as part of the Ministry of Culture administering monuments and archaeological sites (ASI 2018). In 1895, the ASI consisted of five so-called circles, regional units headed by a superintending archaeologist; now there are 27 circles, four of them covering parts of the Plateau. Archaeological research in these northern territories is limited, mostly due to the volatile situation on the border and territorial disputes but also because the harsh environment makes fieldwork difficult.

Research in Nepal is likewise hampered by the harsh environment and political situation, but fieldwork at Buddhist sites there commenced in 1896. In 1953, the Department of Archaeology (DOA) was established for cultural heritage protection and archaeological work. Most work has focused on the Kathmandu Valley, the most thriving part of Nepal located on the northern foothills of the Tibetan Plateau, and most discussions revolve around four topics: the life of Buddha, historical buildings, Paleolithic populations in the lower-elevation areas of Nepal, and connections with other parts of South Asia. Since the 1980s, high-elevation sites in Mustang have been explored in international multidisciplinary projects (e.g., a Sino-Japanese survey in 1986; excavations in Muktinath in the late 1980s and the "High Mountain Archaeology Project" in 1992–1998 by Nepali-German teams; and a long-term project in Samdzong by Mark Aldenderfer and colleagues focusing on the peopling of the Plateau). Taking advantage of the good preservation, much paleobotanical research has been conducted on remains from 1,000 BC to AD 700. Another area of research is the petroglyphs spanning a wide range of dates from the late Holocene to late historic period, studied especially by German teams.

Until recently, archaeological research in Bhutan was not permitted. However, in 2005, the former Prime Minister, supported by the king,

initiated the Bhutan-Swiss Archaeology Project to record and preserve cultural heritage and establish the field of archaeology in Bhutan. So far, most research has concentrated on Buddhist buildings and other aboveground monuments of the sixteenth to twentieth century, but it is to be hoped that in the coming years, some insights will be gained into earlier local developments.

Until fairly recently, there was hardly any contact between scholars from the different countries occupying parts of the Plateau. A first step toward more international collaboration was taken in 2011 when Sichuan University, sponsored by the Harvard-Yenching Institute, organized an international conference on the Prehistory of the Tibetan Plateau in Chengdu, inviting over a hundred scholars from all countries laying claim to parts of the Plateau (mostly China but also Nepal, India, and Bhutan) and a few foreign scholars from Belgium, Germany, Korea, Taiwan, and the USA (Bellezza 2018: Oct. 2011). The 2011 conference raised awareness of research across the borders and established contacts that led to the exchange of publications and unpublished information. Some of the fruits of this exchange can be seen in the 2016 special issue of *Archaeological Research in Asia* which focuses on the Tibetan Plateau.

Key Issues and Current Debates

First Peopling and Human Adaptation

At present, the most contested questions in the archaeology of the Tibetan Plateau revolve around the when, how, who, and why of its peopling. No homo fossils have been found on the Plateau. Absolute dates gained from ostracods on the central Qaidam Basin (c. 31,000 masl) have been dated to 33,000 BP, but some scholars doubt the early date, instead suggesting an occupation from 22,000 BP at the earliest. Human hand and footprints found at Chusang (4,200 masl, NW of Lhasa; Fig. 1, 6) have been dated to 21,700–20,600 BP, but no stone tools or other human-made artifacts have been found at the site. The Dang Valley in Nepal (c. 2,500 masl) has sites with early Acheulean stone tool types; similar stone tools dating to 70,000–40,000 BP have been found in Pakistan but at lower elevations (Darnal 2016). A considerable number of sites from various parts of the Plateau associated with core and flake tools have been assigned to the Paleolithic on typological grounds, suggesting dates of around 30,000–23,00 BP, but direct scientific dates are still lacking for most of these sites. For Xidatan 2, located at 4,300 masl in Qinghai (Fig. 1, 30), recent radiocarbon and luminescence dates have shown that the stone tool assemblages described as late Upper Paleolithic in character date to only 9,200–6,400 BP (Brantingham et al. 2013).

Another point of discussion is the direction of human migration onto the Plateau. Using mitochondrial DNA, Qian et al. (2000) suggest a north/central Asian origin of parts of the genetic pool of modern-day Tibetans but without suggesting any dates. Recently, the discussion has taken a political turn, with several scholars proposing that the ancestors of present-day Tibetans had moved from the Yellow River to the Plateau around 10,000 BP (Su et al. 2000) and that a clear genetic split between the Han Chinese and Tibetans emerged only after 2,750 BP (Yi et al. 2010). The argument for a unidirectional migration from Gansu is based on DNA, linguistic, and archaeological evidence. Su argues that a "Proto-Chinese" group moved into the Yellow River basin between 40,000 and 20,000 BP, developing genetically and linguistically into "Proto-Sino-Tibetan" and moving west in 10,000 BP where around 6,000 BP they became "Proto-Tibeto-Burmans." Van Driem (2002) equates them with the archaeological remains of the Dadiwan agriculturalists in Gansu (Fig. 1, 28) which he sees as "Northern Tibeto-Burmese speakers" who brought cord-marked pottery and polished stone tools, first giving rise to the Majiayao Neolithic in Gansu and eastern Qinghai and moving further onto the Plateau (Fig. 1, 29). Diverging from Su et al., who see all human migration onto the Plateau as coming from the Yellow Rive via Gansu, van Driem sees Kashmir as a second important source of movement onto the Plateau, albeit mostly into its western reaches and its southern rim.

Tibetan Plateau, Archaeology of, Fig. 1 Map of sites mentioned in the text: (1) Chokhopani, (2) Mebrak, (3) Samdzong, (4) Phrang Mgo, (5) Chusang, (6) Chugong, (7) Malari, (8) Yingpanshan, (9) Kharub, (10) Kyunglung, (11) Mkhar gdong, (12) Gurugyam, (13) Xiao'enda, (14) Chufthag, (15) Gebuaisailu, (16) Kanam, (17) Sasongtang, (18) Gelintang, (19) Baishe, (20) Konglong, (21) Dingzhong Zhuizhuzi, (22) Burzahom, (23) Kanishkapura, (24) Bir-Kot-Ghwandai, (25) Ghaligai, (26) Aligrama, (27) Kalaloderay, (28) Dadiwan, (29) Majiayao, (30) Xidatan 2, (31) Lajia, (32) Gufkral, (33) Jiangxigou 2, (34) Taojiazhai

Major problems here are the nature of the evidence and the underlying assumptions. From the archaeological and linguistic point of view, the notion that DNA, language, and ceramic assemblages come in one unified bundle is highly problematic. Furthermore, the model does not explore the reasons for these suggested movements, details of the routes taken, or interactions with people already living on the Plateau. Su et al. and van Driem furthermore ignore the evidence for the presence of Central Asian genes on the Plateau. Analysis on graves from the central Plateau or surrounding areas in statistically significant numbers is likewise lacking (Aldenderfer 2011).

In their argument for a recent genetic split of Tibetans and Han, Yi et al. focus on data from the Northeast with lower-elevation sites such as Lajia (4,000–3,800 BP; c. 1,800 masl; Fig. 1, 31) and Taojiazhai (1,900–1,700 BP; 2,330 masl, Fig. 1, 34) located at the edge of the Plateau and characterized by assemblages showing close connection to the neighboring Yellow River Valley. However, recent genetic data suggests a long-term genetic stability of the inhabitants of Nepal at least from 3,000 BP to the present, as shown by the greater affinity of human remains from Upper Mustang dating between 3,150 and 1,250 BP (Chokhopani, Mebrak, and Samdzong, Fig. 1, 1, 2, 3) to modern Tibetans and Sherpa than to low-altitude East Asian populations (Jeong et al. 2016). Further research on DNA from various periods and parts of the Plateau and surrounding areas will be needed to answer the question of the genetic origin of the people inhabiting the Plateau now and in the past.

Genetic evidence is also of interest for discussions concerning physical adaptations to high-altitude environments. Humans are not naturally suited for hypoxia but have to adapt to it. The exact form of this adaptation seems to differ, as comparative studies between the Tibetan Plateau, the Andes, and Ethiopia suggest. The reasons for those differences are unclear: many depend on the genetic makeup prior to the movement to higher altitudes, elevation, and/or time passed since the initial move.

Based on these genetic processes combined with the archaeological evidence, Aldenderfer (2007) suggests that the movement to higher levels of the Plateau occurred prior to 10,000 BP. This date as well as the sequence and origin of these human movements are contested. Brantingham and colleagues (Brantingham et al. 2013) developed a three-step model: (1) initial stage of occupation below 3,000 masl by mobile foragers moving higher from the Northeast around 30,000–25,000 BP; (2) movement of low-elevation foragers onto the mid-elevation areas (3,000–4,000 masl), pushed higher by agriculturalists after 25,000 BP; and (3) full-scale year-round occupation at elevations over 4,000 masl on the central Tibetan Plateau after 10,000 BP with a system of movement between middle- and high-elevation areas by pastoralists.

Chen et al. (2015) model the advent of agriculture to the Plateau in a similar three-step process: (1) pre-5,200 cal. BP occasional forays of hunter-gatherers onto the Plateau; (2) 5,200–3,600 cal. BP, gradual movement of millet farmers from the Yellow River up to 2,500 m; and (3) arrival of barley and wheat allowing agriculturalists to move over 4,000 masl even under a colder and drier climate.

Both Brantingham et al. (2013) and Chen et al. (2015) have been criticized for their assumption of a unidirectional movement from the northeastern lowlands to the uplands, their disregard for the contribution of local hunter-gatherers, and their extrapolation from a small number of sites in the Northeast to the whole Plateau (Lü 2016). A new set of radiocarbon dates from Chusang at 4,270 masl on the central Plateau suggests that the site may have been part of permanent pre-agricultural occupation around 8,400–7,400 BP (Meyer et al. 2017a) or even 20,000 BP (Zhang and Li 2017).

The Chen et al. model has furthermore been criticized for exaggerating the altitudes at which agriculture would have been possible: d'Alpoim Guedes et al. (2015a) use climatic modeling to argue that millet could not have been grown above 4,000 masl at certain sites as the required number of growing degree-days at minimum temperature could not have been reached. Though it might have been possible to grow millet or barley at some sites, the risk of failure would have been high, so they suggest that barley and millet found in high-altitude sites may have been traded in. For later periods, they suggest that it was only the advent of wheat and barley that allowed for settlement at higher altitudes. In response, Dong et al. (2015) point out that historical records reflect the planting of barley at over 4,200 masl since the early twentieth century. Lü (2016) points to the presence of considerable amounts of millets at the site of Kharub (Karub or Karuo in Chinese; 5,200–3,500 BP; Fig. 1, 9) in eastern Tibet, which he sees as a strong indicator that these were grown locally by settled agriculturalists. He furthermore questions the suggestion that permanent settlement was possible only after the advent of wheat in 3,600 BP, as evidence from sites such as Phrang mgo (Changguogou in Chinese; Fig. 1, 4) in Gonggar, Kharub, and Xiao'enda (Fig. 1, 13) suggests permanent settlement already between 5,000 and 3,600 BP. Lü argues that the models suggested so far may apply to the Northeast, while in the Southeast hunter-gatherer subsistence combined with incipient agriculture was practiced as early as 5,200 BP, with increasing reliance on millets until wheat agriculture entered around 3,600 cal. BP, allowing local populations to withstand the sudden climate cooling.

The main issue in this discussion lies in the small number and uneven distribution of excavated sites, combined with a lack of an established chronology, and a disagreement on methods of modeling. Another issue is the great variability in ecological niches and human adaptations across the Plateau and continued uncertainties about overall climate patterns in prehistoric and early historic periods, combined with the tendency of

scholars to claim that their results won from a limited number of sites apply to the whole Plateau. Another issue not sufficiently explored is the human and cultural component, the choice of specific crops over others, or the potential special use of certain crops in ritual context rather than subsistence, influencing demands on planting success and the amount of crops.

Local Cultures and Shared Traditions

From the material culture point of view, for the Neolithic period, it is clear that there are a number of local traditions in various parts of the Plateau. The most well-researched Neolithic sites on the Plateau are Kharub (3,100 masl, eastern Tibet) and Chugong (Qugong in Chinese, Lhasa, c. 4,000–3,000 BP; 3,680 masl; Fig. 1, 6). Kharub is characterized by a considerable number of houses and large amounts of ceramics and stone and bone tools, the tool assemblages showing similarity to assemblages at lower-elevation sites in western Sichuan. The pottery resembles finds from Majiayao in Gansu, but the nature of this connection is debated. There is evidence for agriculture but also for hunting and in the later phases probably herding and possibly pig domestication. As there are several sites of similar characteristics in eastern Tibet, they are now seen as part of a Kharub culture.

Similarly, Chugong is the type site of the Chugong culture, a phenomenon associated with domesticated sheep, pig, and yak, burnished and often painted fine ware, as well as grinding stones, bone tools, and bronze arrows. The site is interpreted as a local phenomenon loosely connected with Kharub but of later date. Kharub is seen as connected with Majiayao-type sites in lower-elevations Qinghai and Gansu. The connection with lower-elevation Yangshao- or Majiayao-type sites is clear for Jiangxigou 2 (Fig. 1, 33), located at 3,310 masl in Qinghai and characterized by thin cord-marked pottery (from c. 6,900 cal. BP) and millet use (from c. 5,500 cal. BP). The ceramic assemblages at the lower-elevation sites in Qinghai are either attributed to Yangshao (5,000–3,400 BC) or Majiayao (3,400–2,800 BC) influence, but this is likewise a point of contention (Aldenderfer and Yinong 2004).

On the northern Plateau, on highlands of the Qaidam basin, the earliest sites at 2,700–4,700 masl date significantly later (3,400–2,450 cal. BP) and show evidence of barley, wheat, and broomcorn millet growing as well as domestication of sheep, cattle, yak, dog, and horse. Here, too, connections with lower-elevation areas of Gansu have been suggested, in this case with Kayue (c. 900–600 BC), especially in the simple metal axes and knives and to a lesser extent in ceramic assemblages, but the differences are likewise pronounced, suggesting both outside connections and local developments.

A recent survey in Ngawa Prefecture, Southwest Sichuan, has shown an interplay between outside connections and local developments and also on the eastern rim of the Plateau (d'Alpoim Guedes and Hein 2018). The earliest remains found there are settlement sites dating to 3,400–2,000 cal. BC which are exclusively located on the bottom of river valley (below 2,600 masl). They have small house features, polished stone tools, and cord-marked as well as small amounts of painted pottery with likely Yangshao or Majiayao connection (e.g., Baishe, Konglong, Yingpanshan; Fig. 1, 8, 19, 20) combined with evidence for an agricultural way of life (millet, domesticated pig). Medium elevations (2,600–2,900 masl) hold stone-cist graves dating to 1,450–800 ca. BC and lacking any identifiable associated settlement features. High elevations over 3,000 masl are scattered with fragmented pottery sherds dating to 500–1,500 cal. BC with no clear settlement layers. Previously, higher altitudes had been excluded from surveys, working under the assumption that people would avoid such high elevations – an assumption which has now been disproven at least for parts of Barkam. For decades, it has been clear that a dense network of interaction ran along the whole eastern rim of the Plateau, connecting communities living at elevations of c. 1,500–2,800 masl from Qinghai to Yunnan and probably beyond into the Steppe and Central Asia on the one end and Southeast Asia on the other and partially also connecting with lower-elevation locales at least in Qinghai and Gansu (Hein 2014). More fieldwork is needed to assess connections with higher-altitude areas of the Plateau.

For the western part of the Plateau, evidence for permanent agricultural settlement is lacking; what can be seen instead are surface scatters of stone tools, both microliths and polished stone tools, sometimes with heavily fragmented pottery, at altitudes of sometimes over 4,000 masl (e.g., at Dingzhong Zhuizhuzi in Gar County, Burzahom in Kashmir; Fig. 1, 21, 22). Stone tool assemblages usually associated with agriculture have been found across the southern and western rim of the Plateau from western Nepal to Sikkim and have been dated to 1,000–200 BC, though only based on typology (Darnal 2016). In Nepal, Mustang holds sites dating from around 1,000 BC that contain evidence for barley and buckwheat, while wheat, millet, and peas appeared from around 400 BC (Knörzer 2000).

Kashmir has evidence of much earlier human habitation, albeit in its southern reaches. In Ladakh, part of Jammu and Kashmir, Neolithic sites have been found at over 3,000 masl and in great number (e.g., Kiari and Gaik), but excavations so far have been limited. An aceramic Neolithic appears around 2,700 BC. The best researched among the sites located between 1,600 and 1,800 masl are Burzahom (3,000–1,000 BC), Gufkral (aceramic Neolithic 3rd mill. BC, megalithic period 2nd mill. BC, and historic period; Fig. 1, 32), and Kanishkapura/Kanispur (aceramic phase 3rd-2nd mill. BC; ceramic Neolithic 2nd-1st mill. BC; and historic period; Fig. 1, 23), all close together on the foot of the Himalayas (Yatoo 2012). Since the 1980s, several scholars have remarked how different the material from these sites is compared to lower-elevation sites in northern India, while there are notable similarities with contemporary sites in Swat, Pakistan, (especially Aligrama, Bir-Kot-Ghwandai, Ghaligai, Kalaloderay; around 1,900 masl; c. 3,000–500 BC; Fig. 1, 24, 25, 26, 27) (Dani and Masson 1992) but also around Lhasa (Phrang mgo in Gonggar; Yinba in Nedong) and even on the eastern rim of the Plateau at Kharub.

The main connections are the perforated stone knives interpreted as harvesting tools that appear in many sites in eastern Tibet, around Kashmir, the Swat Valley, and Sikkim, associated cultivars such as barley, wheat, millet, lentils, and peas, crops often seen as part of the "Near Eastern package." Lü (2014) argues that, considering the dates of the sites in question, millet must have reached the Lhasa region coming from eastern Tibet which in turn may have received the Near Eastern crop from groups in the upper Yellow River Valley (i.e., Majiayao). Buckwheat, on the other hand, may first have been cultivated on the Plateau, probably before 6,000 BP, be it on its eastern rim or elsewhere. Other evidence for the connection is bone hairpins and jade beads of similar shapes. The ceramic assemblages from eastern Tibet, however, differ markedly from those in the other regions. The assemblages at Chugong and related areas show closer similarities with finds in faraway Kashmir than with nearby Kharub. The nature of these connections between the different regions is unclear, as are the routes that connected them.

It is also remarkable that the stone knives appear in Sikkim as well as Kashmir, but Nepal, located between the two of them, seems to have been "skipped." Most high-elevation material from Nepal known at the present time comes from Mustang (c. 2,500 masl), an area that – in spite of its remoteness – seems to have been integrated into long-distance exchange networks from the mid-first millennium BC at the latest. In Mebrak (c. 400 BC–AD 100), new staples appear such as wheat, millet, rice, and peas for local planting as well as imported plants and plant products such as bamboo, hemp, and lentils (Knörzer 2000). It has been suggested that the earliest inhabitants of Upper Mustang may have come from the lowlands of northern India in the prehistoric period bringing those crops with them (Aldenderfer and Eng 2016), but later migrants may have come from the western Plateau (Lü 2016).

Burial Traditions

Much of the discussion of burial traditions on the Tibetan Plateau hinges on poorly dated burial evidence. Huo (1995) proposed a typology of stone-construction graves, earth-pit graves, and stone-mound and earth-mound graves. He sees the first long phase from the late Neolithic to the sixth c. BC, as characterized by earth-pit graves

and graves with various amounts of stone installations and very few burial goods. In Huo's second phase, stone-cist graves containing double-handled vessels and small stone mounds then become more common from around the fifth c. BC. The third phase is characterized by mounded tombs containing ceramics, stone, bone, and metal items showing close connections to Xinjiang and dating to the 1st–6th c. AD. It is difficult to reach a coherent typochronology for the stone-construction tombs, in particular, due to the lack of absolute dates and the vast range of different grave forms. Furthermore, graves with various amounts of stone installations have been observed over large parts of the mountains of western China and beyond, ranging in date from the second millennium BC to the first millennium AD and associated with a variety of object types and interment practices.

Focusing on reliably dated graves, Aldenderfer (2013) distinguishes two customs: (1) belowground structures appearing from the second millennium BC to the 7th c. AD and occurring over central Tibet, Upper Mustang, the southern Flank of the Himalayas, and the westernmost Plateau; and (2) grave mounds appearing from around 500 BC and in increasing number over the first millennium AD, be it due to outside stimulation or as a local development. Aldenderfer interprets the latter as signs of growing social complexity, expressions of control over landscape and people, culminating in the tomb of the eighth king of the Yarlung Dynasty (c. AD 600). All of these graves differ markedly from mortuary evidence from southern Gansu, challenging the common assumption that new developments on the Plateau mostly originated from the upper Yellow River.

The earliest belowground burials on the Tibetan Plateau proper are known from Chugong in central Tibet, dating to 17,000 BC. They have various amounts of stone installations, containing either primary flexed or more often secondary interments but hardly any objects apart from a few ceramics and in one of the later graves (c. 800–500 BC) a bronze mirror pointing to Central Asian connections (Huo 1995). The tombs of Upper Mustang in Nepal – represented by Chokhopani (c. 1,200–450 BC), Mebrak (400 BC–100 AD), and Samdzong (c. 200–700 AD) – show close similarities with shaft tombs in the far western part of the Plateau and neighboring parts of high-elevation India, all of them showing evidence for secondary burial and at Samdzong de-fleshing, a curious custom not seen in other parts of the Plateau and potentially related to Zoroastrian beliefs (Aldenderfer and Eng 2016) and/or forerunners of sky burial practices emerging around the 9th c. AD.

In contrast to the Chugong finds, both contemporary and later graves in Nepal and the western Plateau are richly equipped. The Chokhopani graves held metal and tooth ornaments, stone tools, ceramics, and copper sheets potentially related to northern India. The Mebrak graves held glass and carnelian beads of South or Southeast Asian origin, bronze ornaments, textiles, wooden items, and sheep and goat bones. Even more animal remains (sheep, goat, caprids, bovids, horse) were found in the Samdzong graves together with metal ornaments, glass beads of Iranian/Sassanian or South Indian/Southeast Asian origin, vessels of bamboo or wood, silk, and in one grave a gold-and-silver mask, finds bearing close resemblance to the assemblages of contemporary graves in the extreme west of the Plateau (e.g., Mkhar gdong Chufthat/Quta, Gelintang, Gurugyam; Fig. 1, 11, 12, 14, 18) and in northern India (e.g., Malari, Kanam, all c. 500–100 BC; Fig. 1, 7, 16) as well as Xinjiang (Aldenderfer 2013).

For the westernmost part of the Plateau, textual evidence attests to the presence of a number of groups along the Yarlung Tsangpo prior to the emergence of the Zhangzhung polity (500 BC – AD 625). In the first c. BC, another political entity arose in the Yarlung Valley, the Yarlung Kingdom or Tubo/Tufan Dynasty. Yarlung and Zhanghuang fought over dominance over the region until the founding of the Tibetan Empire under Songtsen Gampo (604–650 AD). There is a plethora of evidence for this later period, both in Chinese and local text and religious architecture, but there is very little archaeological evidence for the period from c. 1,000 BC to AD 500. Bellezza collected much material for that period through extensive travels, recording hundreds of fortresses, residential and religious building, standing stones, and tombs, unfortunately without

being able to date them reliably. Excavations at the Dindun settlement site and the grave sites of Gebuaisailu and Sasongtang (Fig. 1, 14, 17) provided first radiocarbon dates in western Tibet falling into the Zhangzhung period, c. 400–100 BC (Aldenderfer and Yinong 2004). These sties held various types of stone graves, stone residential structures, and a standing stone. The function and meaning of such stones are debated, especially in their potential connection with deer stones in Central Asia and Mongolia and similarities to megalithic structures in other parts of the world (e.g., Bellezza 2018). Aldenderfer and Zhang (2004) argue that the Central Asian standing stones date to c. 2,000 BC, while those on the Plateau seem to be much younger and look different; the deer stones in Mongolia, on the other hand, are closer in date (c. 1,000 BC–AD 500) as well as form and decoration, potential connections that need to be explored further.

The probable center of Zhangzhung, Kyunglung (also Khyunglung, Qulong, or Qulongcun; Fig. 1, 10) and other residential and mortuary sites in the vicinity are undergoing investigation. In 2012–2014, two cemeteries in Ngari Prefecture dating to the second c. BC and the third c. AD were excavated. Both sites revealed barley seeds and bones of cattle, sheep/goat, and horse, indicating a mixed economy for both locales. Burial customs and contents differ markedly between the two sites. The four cave burials excavated at Chuvthag (Quta; 3,710 masl) in the extreme west of the Plateau resemble graves at other sites in Zanda both in construction and in the high-quality pottery. The excavators argue that these wares resemblance finds in northern India and Ladakh, showing the overall integration of the various parts of the western Plateau now divided by national borders (Tong et al. 2015). The three stone-lined rectangular cave burials containing wooden coffins found at Gurugyam (Guru Jiamu; 4,300 masl) held only few pottery vessels showing some similarity to those from Chuvthag, as well as an iron sword, iron horse bits and arrowheads, bone ornaments, gilt silver ornaments, and glass beads. They have none of the riches found in the Chuvthag cemeteries such as a gold mask, silk items, intricately carved wooden ornaments and containers, complex and numerous metal ornaments and weapons, basketry, and beads made of agate and job's tear seeds. Gold masks have been found in a few other graves on the Plateau (e.g., in Mustang) and in the northern steppe, and the steppe-style handled bronze mirror, wooden-hilted iron dagger, and wooden and basketry items show close ties to Xinjiang and Central Asia, while other items point to connections with Ladakh, similar to the pottery. The beads likewise point to South Asia and the Indian Ocean, reflecting the integration of Chuvthag into a far-flung exchange network in spite of its remoteness. That Gurugyam, located close to the Zhangzhung capital of Kyunglung, should not have been integrated into that network seems strange, but this may simply be a matter of misrepresentation, considering the small number of graves excavated.

Conclusion

Overall, at present genetic as well as historical, archaeological, and linguistic evidence suggest that there were many instances of small- and large-scale movements onto the Tibetan Plateau and between its various parts, partially due to climate change, political instability, wars, or within trade networks. This led to a staggering number of different archaeological phenomena in various parts of the Plateau that are simultaneously uniquely local and closely connected to the outside world.

International Perspectives

As discussed above, the archaeology of the Tibetan Plateau is inevitably an international affair because parts of the Plateau are claimed by a number of countries. Participation in excavations has been difficult for foreigners, especially in Tibet itself. Foreigners are sometimes involved in laboratory analysis, and the archaeologists of Sichuan University, especially, have granted foreign scholars' access to material from Tibet. Research in collaboration with the Academy of Sciences has also been possible focusing on early periods rather than the Academy of Social Sciences usually in charge of archaeological explorations (Chinese-American projects, e.g., by

P. Jeff Brantingham, Richard E. Hughes, David B. Madsen, John W. Olsen, David E. Rhode). Excavations involving foreigners are occasionally possible on the eastern rim of the Plateau in Sichuan (Jade d'Alpoim Guedes and Anke Hein). Non-Chinese areas of the Plateau have seen foreign research involvement, especially Nepal (e.g., Sino-Japanese, German, and American teams, especially Mark Aldenderfer). Most foreign scholars interested in the Plateau, however, either have to repair to Central Asia or lower-elevation regions in Gansu that are politically not contested or rely on published literature. Nevertheless, discussions on the date and direction of the peopling of the Plateau and the movement of agriculture onto the Plateau mainly take place in English and with much involvement of foreign scholars.

Collaboration and indeed communication between scholars from different political entities occupying part of the Tibetan Plateau is rare, partially because of language barriers. The international conference on the Prehistory of the Tibetan Plateau held at Sichuan University in 2011 made great strides toward solving this issue. At the time, hardly anything on the archaeology of the Tibetan Plateau had been published in languages other than that of the country on whose territory the finds were made, but since the 2011 conference, a large number of publications in English have appeared, many of them coauthored by scholars from a number of countries. Most of these collaborations – like most research published in English – focus on the prehistoric period, especially the Paleolithic and early Neolithic, discussing timing of the peopling of the Plateau and human adaptation to the local environment, as reflected in a recent special issue of the journal *Archaeological Research in Asia* (2016 issue 5).

Future Directions

In spite of the recent spike in interest in the Tibetan Plateau, it is difficult to predict where the field is headed. The large number of excavations, surveys, and archaeological discoveries on various parts of the Plateau over recent decades, the increasing number of available absolute dates, the considerable amount of research under way, and the improved possibilities through advancements in genetic research and various forms of scientific analysis suggest that the upcoming years will greatly enlarge the amount of material available, helping us to push forward our understandings of the prehistory and early history of the Plateau. At the same time, the increasingly tight governmental control of research in China and the limitations imposed on foreign involvement in such undertakings as well as the increasing pressure on Chinese scholars to focus on specific state-mandated topics may slow progress. Nevertheless, research in previously neglected areas has recently seen an increase in fieldwork activity such as in western Tibet, eastern India, Nepal, and recently also Bhutan. This can be expected to add much new data in upcoming years, hopefully leading to a better grasp of the chronology of sites and events throughout the Plateau. Given the current trajectory, it can be expected that the great diversity of ecological niches, forms of their exploitation, range of outside contacts, and various cultural expressions throughout space and time will become increasingly more apparent. With such progress, the old tendencies to propose mono-causal, mono-directional models based on observations made at a few sites in a single region of the Plateau will hopefully make way for complex, multicausal models that initially limit their explanation to small, well-researched areas and groups of material with good chronological control and only then engage in multiregional comparisons.

Tikal (Maya): Geography and Culture

Macarena Soledad López Oliva
Santiago, Chile

Introduction

Tikal is one of the most famous and important cities of the Mayan area (Fig. 1), and Mesoamerica in general, and is the largest pre-Hispanic city that exists in Guatemala (Gómez 2013: 10). In addition, it has been one of the most studied by researchers of this culture and has a large corpus of inscriptions that covers from the Early Classic to the Late Classic. It was discovered on February 26, 1848 by the Corregidor de Petén, Colonel Modesto Méndez, guided by the Governor of Petén Ambrosio Tut, who were accompanied by the artist Eusebio Lara to draw the findings (Gómez 2013: 10).

Projects and Scientific Researches

Since it was discovered in the mid-nineteenth century to the present, Tikal has been studied by various researchers and scientific projects. The first plan and the first photographs of Tikal were made by the Englishman Alfred Maudslay, between 1881 and 1882. Between 1895 and 1904, the German Teobert Maler, of

Tikal (Maya): Geography and Culture, Fig. 1 Map of the Maya territory, with the location of Tikal. (Map by Harri Kettunen)

the Peabody Museum of the University of Harvard, increased the photographic registry and of drawings. Alfred Tozzer, from the same museum, made the map of Tikal, which was published in 1911 (Gómez 2013: 10–11). From 1914 to 1937, Sylvanus Morley conducted research in the northwest area of Petén, including Tikal. Scientific studies in this city began in 1956, with the Tikal project, by the Museum of the University of Pennsylvania. This project focused mainly on the core of Tikal (Great Plaza, Temples I and II, and the North and Central Acropolis) (Fig. 2) and in some housing groups. In 1961, the Tikal project published an excellent plan of the city (Tikal Report No. 11) (Fig. 3). Later, in the 1970s, a group of Guatemalan researchers continued with scientific investigations (excavated and restored Group G or 5E-11), and during the years 1979 to 1985, the Institute of Anthropology and History organized the National Project Tikal, under the direction of the archaeologist Juan Pedro Laporte. The Tikal National Project focused especially on the Plaza of Lost World and various interesting housing groups south of the Plaza (Iglesias, July 2019, personal communication). From 1992 to 1996, some works continued in the city, with international cooperation agreements with Spain, through the Spanish Agency for Cooperation. These works focused on the consolidation of Temple I and the excavation and restoration of Temple V.

During the years 2003–2006, the "Project Study of the Archaeological Fortifications of Tikal" was developed, directed by David Webster and other researchers. In 2002, another agreement was signed with Spain to investigate and preserve the Plaza of the Seven Temples. In 2005, the Archeology Unit of the Tikal National

Park began the restoration and research works of Temple IV, the largest building constructed by the Mayan culture in a single moment. In 2009, several researchers (Lentz et al. 2015) started a new project to investigate silvicultural and water management practices of the ancient Tikal (Gómez 2013: 11–13). Since 2013, the "Petén Epigraphic Atlas Project" has been developed, with the collaboration of the Russian-Guatemalan Center for Mayan Studies Yuri Knórosov (CEMYK); the Institute of Anthropology and History (IDAEH), of the Ministry of Culture and Sports; and some researchers of the Center for Mesoamerican

Fig. 4 Emblem glyph of Tikal, known as Mutu$^{?}$l in the Classic, with its main sign, the Logogram **MUT**. Stela 5 detail, drawing by Diego Ruiz Pérez

Studies of the Russian State University for the Humanities (Moscow); the Corpus of Maya Hieroglyphic Inscriptions Program of the Peabody Museum, Harvard University; and the University of San Carlos from Guatemala (Beliaev and De León 2013: 13).

All these investigations and many more have contributed to build the extensive knowledge that is currently known about this city.

Definition

The toponym of Tikal is relatively modern, and according to Martin and Grube (2008: 30), it derives from the Yucatec Maya *ti ak'al*, meaning "at the water hole," maybe in reference to one of the city's ancient reservoirs; however, it could also come from *ti' 'ik'al*, which in the same language means "place of spirits" or "place of winds." Legend says that the inhabitants "of the 19th century settlement were driven out of their humble houses in the ruins by a combination of fear of the 'spirit voices' and a plague of bats (…) It is possible that an outbreak of rabies may account for the virtual abandonment of the site by the Maya re-occupants in the mid-19th century" (Harrison 1999: 30).

Apart from this name, there was another toponym with which the ancient Maya identified the site; this toponym conformed part of the emblem glyph (Fig. 4), known in the Classic (250–900 AD) as Mutu$^{?}$l. The Tikal emblem glyph main sign, the logogram MUT – deciphered independently, in the year 1993, by Stuart and Prager, thanks to the phonetic complementation **mu-**, **-tu** – originated as a representation of a tied hair (Stuart 2013), and the meaning of that word could be "hair" or "type of hairstyle"; nevertheless, the precise meaning of this word remains uncertain. In addition, some years ago Beliaev, based on the text of Stela 31, proposed a new reading of the emblem glyph of Tikal as **KUK** instead of **MUT**. According to him, the ancient name of Tikal should be read *Kuku$^{?}$l* or *Yax Kuku$^{?}$l* (Beliaev and De León 2013: 45), but this proposal is still under discussion.

Tikal is located in the central zone of the Petén Department, Guatemala, in an extension of territory with low population density (9.19 inhabitants per km^2, which represents 2.7% of the total population), which contributes to maintaining the largest virgin forest reserve in the region; for this reason, it was declared a National Park in 1955. The Tikal National Park covers an area of 576 km^2 of tropical rain forest, in whose center the old Mayan city of Tikal is located and some other small cities that were controlled by the Tikaleños governors. This park, together with other protected areas, forms the largest natural reserve in

Mesoamerica, called the Mayan Biosphere, of approximately 21,000 km^2 (Gómez 2013: 9). In the National Park inhabits a great diversity of flora and fauna, including important wetlands recognized worldwide and a series of limestone hills that rise over swampy or lowlands, with a rolling terrain ranging between 100 and 300 m a.s.l. (Beliaev and De León 2013: 15). The geographical situation of Tikal allowed it to develop into a Mayan city of great extension and outstanding architecture. The city is located on a meseta in the hydrographic zone of the Yucatan Peninsula. "With the construction of Tikal in that location, through which passed one of the interurban roadways that linked the network of tributaries of the Usumacinta, to the west, with the Caribbean, to the east, the inhabitants of the city took control of long distance trade" (Harrison 2011: 219). The main architecture of the site is grouped in the highest areas that are interconnected by roads that cross the marshes (Beliaev and De León 2013: 15). Because of its indisputable cultural and natural importance, Tikal was declared a World Heritage Site by the United Nations Educational, Scientific, and Cultural Organization (UNESCO) in 1979, constituting the first Mixed Cultural Heritage Site (cultural and natural) in the world (Gómez 2013: 9).

The archaeological site Tikal was one of the most important Mayan cities of the Classic period; it extends for more than 16 km^2 and houses about 3,000 structures of different functions: temples, palaces, ball games, residential structures, and astronomical commemoration complexes, among others (Fig. 3). The site is located at 283 m a.s.l. and at a distance of 495 km north of Guatemala City, 64 km from the city of Flores, 19 km south of the Uaxactún archaeological site, 30 km northwest of Yaxhá, and 100 km southeast of Calakmul, the city which perpetuated a fierce struggle for the political hegemony of the Maya Lowlands throughout the Classic period (Beliaev and De León 2013: 15).

Historical Background

The first occupation of Tikal corresponds to the Middle Preclassic (900–600 BC) (Laporte and Fialko 1993: 9), also known as the Pre-Mamon Horizon, in the area known as the Lost World. Although the first settlements correspond to that time, the area had an uninterrupted activity until the Terminal Classic (800–950 AD).

In the earliest moments of his occupation, the Lost World had an important ritual character, reflected in the first development known for a complex specialized in astronomical commemoration (Laporte and Fialko 1993: 9), through the construction of a relatively small group of buildings, known as "E-Groups" (Harrison 1999: 53). Later, in the Late Classic (600–900 AD), the function of this complex changed toward another type of civic manifestations (Laporte and Fialko 1993: 9).

Very little is known about the occupation of the Preclassic in Tikal, due to the few housing centers that have been investigated. This is perhaps related to the massive leveling and construction caused by the constant growth of the ceremonial sectors, which perhaps destroyed nearby and earlier housing areas, to use their material as a filling of squares and structures (Laporte and Fialko 1993: 9).

The pioneers of Tikal established the basis of their civilization at this site with most of its basic characteristics by 350 BC. Toward I AD, Tikal manifested all the character traits of the Maya high civilization. A big change affected their population during the last three-and-one-half centuries BC, lasting for the next 250 years (Harrison 1999: 53).

During the Late Preclassic (350 BC–250 AD), the North Acropolis (Fig. 2) remained the largest constant focus of architectural growth on the site, establishing this part as the heart of Tikal and as a place of burial of kings and a growing cosmic expression. "The Lost World Pyramid group to the southwest of the North Acropolis was the other location of important growth" (Harrison 1999: 53).

The dynastic history of Tikal, and of many Mayan cities, has been reconstructed, thanks to the narrations in the monuments (mainly stelae) written in hieroglyphs: the deciphering of the hieroglyphic writing and the later development of the Mayan epigraphy have been and are fundamental, to understand the past of this complex culture.

The dynastic history of Tikal, which begins in the Early Classic (250–600 AD), includes a succession of 33 kings who ruled their political territory for 800 years (Martin and Grube 2008: 25). The dynasty was founded in 90 AD, with Yax ʔEhb' Xook, who perhaps came from the dynasty of the neighboring city of Uaxactún, with which Tikal maintained good relations throughout its history (Gómez and Kováč 2016: 38–40, 42).

Stela 29 is the earliest of those found in this era (292 AD), and in it is mentioned for the first time the *ʔajaw* or "lord" of Tikal, the title used by the Mayan kings (Martin and Grube 2008: 26–27).

Very little is known of the first 13 kings of the Tikal dynasty; of the 13th, K'inich Muwaan Jol, it is only known that he was the father of his successor (indicated on Stela 39), Chak Tok ʔIch'aak I (14th Ruler), a king with whom, and despite him, the story of Tikal in the Early Classic changed drastically. This king probably enthroned the 360 AD and "presided over the largest and most progressive of the new Classic Maya cities. Part of this success was undoubtedly due to long-distance trade, not only that with the Maya highlands to the south but with distant Mexico and the powerful city of Teotihuacan. There are signs that imported Mexican architectural styles had already taken root at Tikal by this time and even hints of intermarriage between the two ruling elites. But Tikal's relationship with its western partners was about to change dramatically, and the lowland Maya would soon be drawn into a much wider Mesoamerican scheme" (Martin and Grube 2008: 28).

Toward the end of the fourth century, in 8.17.1.4.12 11 ʔEb' 15 Mak (January 16, 378 AD), Tikal fell under the power of Teotihuacan with the arrival of Sihyaj K'ahk' to this political capital. This Teotihuacan political conquest was supported by Mayan allies, since 2 days before the famous date – which indicates the arrival of Sihyaj K'ahk' to Tikal and the death of the ruler of that city, Chak Tok ʔIch'aak I – the king of Naachtún declares himself, on Stela 24 of his city, the yajawteʔ or "captain of war" of Sihyaj K'ahk' (Nondédéo et al. 2016). These facts meant, on the one hand, that both Tikal and a large sector of the central area were more involved in the political, cultural, and economic sphere of Teotihuacan, at that time in its heyday, and, on the other, that a new Mayan-Teotihuacan dynasty consolidated Tikal as a leader in the region (Martin and Grube 2008: 29).

The death of Chak Tok ʔIch'aak I ended his entire lineage, as he was replaced by a new male lineage, probably originally from the ruling house of Teotihuacan (Martin 2003: 12). The impact of the conquest was noted, since most of the monuments of Tikal were destroyed and others were dispersed to peripheral cities, such as El Encanto, Corozal (Martin 2003: 15), El Temblor, and Uolantún, where Stela 36 was found.

Although Sihyaj K'ahk' became the master of Tikal, he was never enthroned, since he installed as ruler Spearthrower Owl's son (Martin 2003: 15) – another important Teotihuacan character who apparently married a lady from Tikal – Yax Nuʔn ʔAhiin I, the king who established a new Teotihuacan dynasty in the city and who performed the first impersonation ritual recorded in Tikal and throughout the Mayan area, thus inaugurating the practice of that ritual, on November 5, 406 AD (López 2018: 45, 47, 826: Tabla XI.4, 940). The impersonation ritual is a universal religious phenomenon and consists of the incarnation, through the possession, of a god or supernatural being in a person's body. It was done to achieve a theophany, that is, the concrete manifestation of a deity or a supernatural being in the world of human beings. The establishment of this ritual originated the conception of a sacred, divine monarchy, that is, a theocracy, and it became a political factor of the first order in the Mayan area (López 2018: 928–929, 931).

After the death of Yax Nuʔn ʔAhiin I, on November 27, 411, his son was enthroned, Sihyaj Chan K'awiil II. On Stela 31 he carries a complex headdress with the crest of Yax ʔEhb' Xook, thus explaining his declaration of dynastic restoration, since in it he "proclaims the rebirth of orthodox kingship, neither sullied nor diluted by its foreign blood, but reinvigorated" (Martin and Grube 2008: 34). But this situation changes with the government of his son, K'an Chitam, who assumed power in the year 458, after the death of his father. K'an Chitam's texts do not

mention external matters, but if he was still in power in August 486 (the date of death of this king is unknown), he would have directed the attack of Tikal against the northern city of Maasal. This is one of the first wars described in the Maya inscriptions (Martin 2003: 16–17). In addition, with K'an Chitam the use of the staff stelae monuments began (Guenter 2002: 26).

This king was in charge of continuing the legacy of his grandfather Yax Nuʔn ʔAhiin I, ignoring the dynastic restoration that his father intended to establish, and for this he made the second impersonation attested in Tikal, recorded on Stela 9 (López 2018: 61), with which the practice of this ritual is standardized.

After K'an Chitam his son governed in Tikal, Chak Tok ʔIch'aak II, who died in July 508, and, later, Lady York'in of Tikal, who almost certainly was his daughter and was enthroned in 511 at 6 years of age, but apparently never governed by herself, but co-ruled with one or more men. After the death of Chak Tok ʔIch'aak II, the next half century was a time of dynastic riots, period also known as the "Middle Classic" of Tikal (508–562), since it took 30 years for the son of this king, Wak Chan K'awiil (the 21st Ruler), to claim his position. The "Middle Classic" of Tikal was a problematic time and little is known about, since the monuments are poorly preserved and some were deliberately damaged (Martin and Grube 2008: 37–38).

K'inich Waw?, possible 20th Ruler of Tikal, would have ruled sometime between 527 and 537 (Martin and Grube 2008: 39). In the only monument of his government, Stela 8, appears the third impersonation registered in Tikal (López 2018: 70):

> Architecturally, we know that there were major developments during the Middle Classic era, with the building of the large East Acropolis platform and new plaza floorings throughout the central zone. The first twin-pyramid complex, a special arena for K'atun-ending ceremonies, was also added in the East Plaza at this time. (Martin and Grube 2008: 39)

Under the reign of Wak Chan K'awiil, Tikal was defeated in a war in 562, apparently by Dzibanché, the lords of K'anuʔl at that time. With this event Tikal's dominance in Petén ended, and the city sank into a long dark epoch; possibly Wak Chan K'awiil was sacrificed (Sharer 1999: 218). For the next 130 years, no monuments dating from Tikal have been found; this silence is known as the hiatus from 592 to 692, which has been linked to the fall of Teotihuacan in this period and with the idea of a "small collapse" or perhaps a "domino effect" in the Mayan area. But the military submission of Tikal coincides with the rise of a great rival in Petén: Calakmul (Martin and Grube 2008: 40).

Wak Chan K'awiil was succeeded after the year 562, by "Animal Skull" or K'nich Waaw according to Guenter (2002: 96), the 22nd Ruler. The maternal lineage of this king was the sustenance of his legitimacy to the throne (Martin 2003: 25), breaking with the previous lineage, established with the arrival of the Teotihuacans. Shortly after his death, in the year 629, Tikal founded the city of Dos Pilas and sent his future king, B'alaj Chan K'awiil (Demarest y Fahsen 2003: 165). This period, which was under the reign of Nuʔn ʔUjol Chaahk of Tikal, was characterized by diverse fights between Tikal, Calakamul, and Dos Pilas, the latter supporting at the beginning Tikal, but later, under the supremacy of Calakmul after being conquered in 659, it acted against Tikal (Fahsen et al. 2003: 686, 690).

Nuʔn ʔUjol Chaahk's son, Jasaw Chan K'awiil I, succeeded him on the throne in 682. Under his direction "the city grew as never before and its army managed to placate its enemies and stabilize the region" (Gómez and Kováč 2016: 43). In addition, this ruler linked his kingdom to the heyday of Tikal's past associated with Teotihuacan and had a decisive victory over Calakamul in 695, which began the decline of the hegemony of Calakmul and the rebirth of Tikal as a war power (Martin and Grube 2008: 44).

After the death of this king, in the year 734, his son was enthroned, the 27th Ruler, Yik'in Chan K'awiil, who continued with the imperial ambitions of his father and transformed the city, overshadowing those of his rivals: he built a new tomb for his father and probably erected almost all the causeways that interconnected the main areas

of the city; he built and remodeled Temples IV and VI, Group 3D-2, and the East Market complex, made important additions to the Central Acropolis, and built or renovated almost all the great palaces surrounding the center of Tikal (Harrison 1999: 149, 158–159, 162).

This king was one of the greatest military heroes of Tikal. On Stela 21, his image appears with a captive from Calakmul, maybe the same king, since at that time there was a change of power in that city. In 743 he attacked Yaxa?, a satellite of El Perú, defeating his king; almost 200 days after, Yik'in Chan K'awiil attacked Naranjo and captured his king, Yax Mayuy Chan Chaahk. These victories broke the hostile encirclement of the kingdom that endured for at least a century. As both cities were important allies of Calakmul, their rapid defeat apparently is explained due to the diminishing powers of Calakmul. This new supremacy over the Petén fostered the construction boom through perhaps booties, tributes, or conscript labor (Martin and Grube 2008: 48–50).

During the government of this king, the last impersonation, known until now, is recorded in Tikal, in Lintel 3 of Temple IV, or Structure 5C-4 (López 2018: 77–98), Yik'in Chan K'awiil's biggest temple (64.6 m high) and the highest pyramid in America (Fig. 5) (Harrison 1999: 153–154).

The duration of the government of Yik'in Chan K'awiil is unknown, but later, his sons succeeded him, the 28th Ruler – who very little is known – and Yax Nu?n ?Ahiin II, who was enthroned in 768 and built the twin pyramids Q and R during his tenure (Martin 2003: 32). By this time, the Tikal dominion over the Central Petén begins to diminish.

At the beginning of the ninth century, in the Terminal Classic, signs of a deep crisis appeared, with the disappearance of the dynasties of the region and the vertiginous diminution of the

Tikal (Maya): Geography and Culture, Fig. 5 Temple IV of Tikal in the far distance. (Photograph by Diego Ruiz Pérez)

population. This greatly affected the Tikal dynasty, of whose four kings (Nuʔun ʔUjol K'inich, "Dark Sun," "Jewel" K'awiil, and Jasaw Chan K'awiil II) very little is known (Martin and Grube 2008: 52–53).

In the late ninth century, Tikal suffered the same fate as his contemporaries in the Mayan area. All vestiges of royal power disappeared, and the elite neighborhoods remained semi-deserted, being occupied by squatters who built huts in ceremonial plazas. These last inhabitants continued with their complex ritual activities reusing and moving the ancient monuments; also no consideration of sanctity of the old order disappeared, since several tombs of the North Acropolis were sacked. The city was abandoned in the tenth or eleventh century, being finally buried by the jungle (Martin and Grube 2008: 53).

Key Issues/Current Debates

The arrival of the Teotihuacan to Tikal is quite controversial because the epigraphic version, according to some authors, is not supported by the archaeological record of the city (Iglesias 2003).

After analyzing problematical deposits and some Tikal tombs, Iglesias concludes that "The data derived from the problematical deposits and burials reflect the dominant culture of the elites of Tikal during the late Early Classic period, a material culture that is overwhelmingly of local origin. In contrast, the presence of foreign elements is extremely minimal (. . .) Archaeological data supporting the notion that Tikal contained a Teotihuacan 'enclave' or was an important 'interactive node' in a large-scale, Teotihuacan-focused network have been greatly exaggerated. Assuming that inter-elite contacts existed, their effects on both sociopolitical and cultural development at Tikal were quite literally immaterial (. . .) What is lacking at Tikal is evidence that Teotihuacan had any lasting impact on material culture" (Iglesias 2003: 192–195).

These data lead to Iglesias to reevaluate the importance of Teotihuacan's influence on Tikal and the Mayan area in general, although it is confirmed by certain findings (Iglesias, 2017, personal communication), including the possibility of the physical presence of Teotihuacanos in certain Mayan cities (Iglesias 2003: 191). Contrary to these approaches, there are archaeologists and epigraphists who endorse the presence and influence of Teotihuacan in the Mayan area and in Tikal, based, on the one hand, on the hieroglyphic inscriptions of various Mayan cities that mention the arrival of foreigners from Central Mexico in the zone, at the end of the fourth century (Stuart 2000), and, on the other hand, in the archaeological evidence of Teotihuacan influence, such as talud-tablero temples; typical Teotihuacan architecture; royal burials in Teotihuacan style, for example, in the city of El Zotz – located 20 km west of Tikal (Garrison en Dashwood et al. 2018: 45'-51'); stone monuments; ceramics; and other types of portable material culture (Coggins 1975: 253). All this would indicate that the Maya of this region began to adopt the Teotihuacan culture, the influence of which is evident. On the other hand, the establishment of the impersonation ritual in the Mayan zone, which begins with Tikal, strongly points to having been imported by Teotihuacanos (López 2018). Within this controversy Yax Nuʔn ʔAhiin I king is directly inserted and with him, the possible establishment of a new Teotihuacana dynasty in Tikal: the discussion is still open.

International Perspectives

The dynamic system of the Maya Lowlands extended slowly from its core of the central area, Petén. After the period of Teotihuacana intervention, toward the end of the fourth century, the rate of expansion increased markedly. The new kingdoms, many already established since the Preclassic, occupied most of the productive lands of the Mayan area. They were extremely individualistic; they had their own pantheons of divinities and mythical history, inherited from the preclassical traditions. These political entities were the largest stable units that emerged during the six centuries of the Classic; however, due to the

constant conflicts, the Mayan territory was never unified under a single authority (Martin and Grube 2008: 18).

In this context, there were pervasive and enduring systems of "overkingship" that influenced almost all facets of the Classic panorama. This scheme agrees with a widespread practice in Mesoamerica and explains the overwhelming evidence of numerous small kingdoms with the great inequality observed in the size of their capitals (Martin and Grube 2008: 19).

Although Tikal was one of the most important political entities of the Classic, it was not the only one, since Dzibanché and Calakmul (cities ruled by the kings of the K'anuʔl lineage at different times) always disputed with Tikal the hegemony of the Mayan zone. These political entities were the main twin superpowers of the Mayan area and had a significant influence on the political relations of most of the cities in the area. These relationships were reflected through the various events that occurred throughout history, where wars, marriage alliances, rival factions, and allies abounded. But these relationships were generally not lasting and depended on various economic, political factors, family ties, etc. In this way, many political entities were allied with Tikal in one moment, but in another, with Calakmul and vice versa. This reflects the complex political landscape that the Maya lived throughout their history in the Classic.

Future Directions

The knowledge of Tikal and the Maya culture in general is due mainly to two great disciplines: epigraphy and archeology. However, in recent years, with the great advances of Maya hieroglyphic writing, epigraphy has stood out and greatly influenced the interpretation of the history of Tikal, sometimes even to the detriment of archeology. This has caused, at times, that both disciplines distance themselves and even face each other, with opposing postulates, as, for example, the one analyzed on the Teotihuacana influence. According to Guenter (2002) and Moholy-Nagy (2016), currently, the archaeological evidence of Tikal contradicts the supposed general decline that would have occurred during its longest hiatus (527 to 692, also known as the hiatus from 592 to 692), as well as the historical explanation of its cause, widely accepted by the Mayanists, which would indicate, according to the epigraphic texts, that it occurred due to the wars and the structural political instability that affected the Mayan zone, being Tikal one of its main protagonists. On the contrary, the archaeological evidence indicates that this period was a general period of material prosperity and cultural innovation (Guenter 2002: 96; Moholy-Nagy 2016: 255) and that the causes of the hiatus would have been internal (probably caused by fights between rival lineages of Tikal) and independent of the military defeats recorded in the texts (Moholy-Nagy 2016: 260, 262).

These contradictions between epigraphy and archeology must be evaluated together, to try to unify the discordant evidences that sometimes appear in both disciplines.

Time Since Death in Bioarchaeology and Human Osteology

Shari Forbes and Maiken Ueland
Centre for Forensic Science,
University of Technology Sydney,
Sydney, NSW, Australia

Introduction and Definition

Time since death (TSD) is defined as the time frame between death and discovery of an organism. When estimated in an archaeological context,

this time frame may be referred to as time since deposition and in a forensic context can be termed postmortem interval. Time since death cannot be established with certainty and for this reason is provided as an estimate of the range of time encompassing the period when death occurred. A shorter postmortem interval is typically associated with a narrower time range, while a longer postmortem interval has a broader time range and includes a wider margin of error. Presently, there is no single indicator which provides a reliable or accurate measure of the time since death of an organism.

Key Issues and Current Debates

Current Methods for Estimating Time Since Death

In a forensic investigation, the most reliable estimates of time since death are based upon observations and measurements made by a forensic pathologist during an autopsy. Physical and anatomical changes such as algor mortis (process of body cooling), rigor mortis (process of muscle stiffening), and livor mortis (gravitational blood settling) can be used for TSD estimation. In addition the analysis of the gastric contents and vitreous humor may also assist in estimating the time frame of death. Depending on the surrounding environmental conditions at the time of death, these indicators are often only applicable for the first few hours to days following death. During this period, the process of decomposition will commence, and the pathologist will use collective biochemical indicators such as autolysis, putrefaction, and liquefaction to assess the stage of decomposition and thus approximate time since death.

The process of decomposition will attract insects to the remains if the body is in an accessible location. The life cycle of insects can also be used to estimate time since death through the discipline of forensic entomology. The TSD estimate may span days, weeks, or months but becomes limited once insect activity has ceased. Forensic entomologists typically use alternative terminology to denote the stages of decomposition which includes fresh, bloat, active decay, advanced decay, and dry/remains or skeletonization. Until the point of skeletonization, both the forensic pathologist and entomologist rely on the biochemical degradation of soft tissue to assist with the estimation of a minimum TSD.

Effect of Decomposition on the Estimation of Time Since Death

Once soft tissue has completely decomposed and the remains are partially or completely skeletonized with only hard tissue (i.e., bone) remaining, the estimation of TSD becomes increasingly difficult, with longer estimation windows and larger uncertainties. When analyzing evidence that is very old, the archaeologist or anthropologist must interpret how the condition of the remains at the time of discovery has varied since the time of deposition. This requires an understanding of decay rates and the taphonomic processes which can act on the remains over time.

Nawrocki (1995) identifies three major classes of taphonomic processes when dealing with human remains recovered from a historical period: environmental, individual, and cultural factors. Environmental factors (e.g., temperature) are external variables which can act on the remains and are specific to the geographical region and microenvironment in which the process of decay occurred. Individual factors (e.g., body weight) originate with the deceased person and can also contribute to the decomposition process. Cultural factors (e.g., embalming) relate to the mortuary activities following one's death. Most of the time, these classes are mutually exclusive; however, certain factors may be classified under more than one class.

Environmental factors can be further divided into biotic and abiotic factors (Nawrocki 1995). A biotic factor refers to any living component that acts on another organism. Biotic factors which can act on soft and hard tissues are numerous and include scavenging and chewing by carnivorous animals, dispersal and fracturing by burrowing animals, tunneling by plant roots, and microbiological degradation by bacteria and fungi. Abiotic

factors are the nonliving components which act on the organism such as temperature, moisture, light, wind, altitude, and soil pH (Ubelaker 1997).

There are many factors specific to an individual which cause variation in bone decomposition and subsequently hinder the estimation of time since death. Different bones within the body, and even different areas of the same bone, will show variation across an individual. Some bones will be dense (cortical), while other bones will be spongy (trabecular) yielding a larger surface area per volume of bone which is subjected to degradation. As a result, cortical bone tends to resist degradation better than trabecular bone. Additional factors which may affect the degree of skeletal degradation or preservation include antemortem disease, perimortem trauma, and body size differences resulting from age and gender (Nawrocki 1995).

Cultural factors are unique to humans and can include the preparation of the individual following death, burial below ground or in vaults or tombs, or cremation of the remains. The process of burial in a coffin can enhance soft and hard tissue preservation. Burial is known to slow the rate of decomposition when compared to remains left on the soil surface (Forbes 2008). Reduced decomposition is predominantly the result of restricted access to vertebrate and invertebrate activity; however, the coffin can also act as a barrier, thus protecting the bone from the impact of surrounding soil and vegetation. Since animal carcasses on the surface are often rapidly scavenged, scattered, and dispersed, only buried remains typically become part of the archaeological record. The act of burial may improve the estimation of time since death by preserving the skeletal material but, in doing so, also makes the study of human remains considerably more complex.

Behrensmeyer's (1978) stages of bone weathering represent one of the more commonly utilized methods for estimating time since deposition of bone. During research investigating mammal bones in the Amboseli Basin of southern Kenya, Behrensmeyer identified six stages of bone weathering. This model has been used to better understand and reconstruct the archaeological record of animal remains. While not commonly employed in a forensic context, the model can assist in differentiating weathering effects on bone from perimortem trauma (Ubelaker 1997).

Effect of Preservation on the Estimation of Time Since Death

Preservation of human remains as a result of natural or cultural processes can reduce the accuracy of time since death estimations if not accounted for. Natural preservation of soft tissue can result from desiccation (rapid drying), freezing and sublimation (freeze drying), adipocere formation, and fixation by tannic acids (Sledzik and Micozzi 1997). Cultural preservation may involve elaborate methods for preserving both soft and hard tissue or may simply involve the injection of chemicals for embalming and funeral purposes. In the archaeological record, one or more of these factors can act on the body over time, and it is not uncommon for archaeological human remains to be mistaken for forensically significant remains when first discovered due to their excellent preservation.

The processes of desiccation and sublimation rely on the rapid loss of moisture. Desiccation results from the drying out of soft tissue in hot, dry climatological regions and can affect the entire body or specific areas of the body depending on the degree of exposure. Mummification is the product of desiccation which restricts postmortem decomposition and promotes preservation of both soft and hard tissue. Climates conducive to mummification have been found in South America (e.g., Chile and Peru), southwestern USA, the desert regions of Africa, and the outback of Australia (Sledzik and Micozzi 1997). Mummification can also occur in enclosed environments, and an understanding of this process is important in forensic investigations when estimating time since death. Mummification of recently deceased remains can occur in apartments or houses whereby the continuous heating during winter months produces a hot, dry internal environment.

Sublimation is typically observed in cold or freezing environments and results from the transformation of frozen water to a gaseous phase in soft tissue coupled with the inhibition of

decomposer organisms. Regions conducive to natural sublimation include the Arctic and Antarctic circles as well as cold, high-altitude environments. One of the best known natural mummies of the world, "Ötzi – the Iceman," was discovered in a cold, dry environment in the Ötztal Alps along the Italian-Austrian border (Fleckinger 2010). The excellent preservation of soft tissue allowed for the dating of his remains, demonstrating that he is among the oldest, and most well-preserved, natural mummies ever discovered. Dating remains of archaeological significance is readily achieved as typically only an approximate estimation is required (±100 years). On occasion, forensically significant remains are discovered in cold or freezing environments, demonstrating a "fresh" appearance which contradicts their true postmortem interval. However, it is unlikely that sublimation would occur in a forensic context, simply due to the length of time required for the process to be complete (Sledzik and Micozzi 1997).

Adipocere formation is a commonly encountered phenomenon in wet environments; however, its formation is not restricted to waterlogged locations (Forbes 2008). Adipocere results from the chemical degradation of adipose tissue to produce a solid, stable product comprising predominantly saturated fatty acids. Adipocere formation is associated with the inhibition of decay, and as a result adipocere-laden corpses are resistant to decomposition. Adipocere can form over the entire body or can be restricted to specific parts of the body depending on the amount and translocation of neutral fats within an individual. Similar to other types of natural preservation, its preserving effects can aid the recovery of soft tissue in the archaeological record, but can complicate the estimation of time since death in a forensic investigation. Adipocere formation can be valuable for suggesting a minimum amount of time since decomposition and can also provide information about the depositional environment (Forbes 2008).

Peat bogs represent an alternative preservation environment often encountered in the archaeological record. Both human and animal remains have been discovered in wetland peat deposits, demonstrating varying degrees of preservation and a range of trauma and pathology (Brothwell and Gill-Robinson 2002). Preservation is thought to result from the action of humic acids and the reduced aerobic and bacterial nature of bogs. To date, more than 2,000 finds have been recorded with the majority of bodies discovered across Northern Europe. Estimating the time of deposition for bog bodies is achieved using radiocarbon dating so as to place the remains in a particular time sequence or era. Many of the recovered bodies have been dated between 800 BCE and 100 CE, and there still remains considerable debate about the reason for their deposition. More recently deceased victims are occasionally discovered in peat bogs; however, they rarely display the same level of preservation as historical discoveries.

Future Directions

Research over the past century has focused on improving the accuracy of time since death estimations. Thanatochemistry is a term commonly used in forensic pathology to describe the postmortem chemical processes which occur in the body. Studies in this area have focused on chemical, biochemical, biological, and microbiological methods for accurately determining the time of death. Forensic entomology has also emerged as an acceptable method for estimating TSD. However, there are still errors associated with this method due to the lack of well-established databases and the fact that the attraction mechanism of insects to the body is still unknown. The combination of a range of these methodologies is currently the most accurately available to the field of forensic science.

A range of alternative methods have been investigated to assist with estimating time since death in forensic investigations. A large focus has been placed on developing semiquantitative methods of estimating TSD, rather than observations of decay. Several scoring systems based on the physical changes have been developed. These include empirical formulas such as the universal formulas developed by Vass (2011) and total body

scoring (TBS) systems such as that developed by Megyesi et al. (2005). TBS divides the body into three regions (head, trunk, and limbs), and the visual decomposition changes are scored according to a rubric for each region. Both the universal formulas and TBS provide good estimations of TSD in the geographical region where they were created; however, when they are attempted in different geographical regions, they often over- or underestimate the TSD (Cockle and Bell 2015). One trend that is becoming norm for time since death investigations is the use of accumulated degree days (ADD) to compensate for temperature differences during different seasons or climates. ADD is the cumulative total of the average daily temperatures that the body has been exposed to over time and has been found to explain much of the variation in decomposition observed between different bodies (Megyesi et al. 2005).

Decomposition chemistry represents a variation of the field of thanatochemistry whereby studies focus on the chemical and biochemical degradation of soft tissue across the entire decomposition period. Studies have investigated the use of a variety of chemical classes such as volatile-, short-, and long-chain fatty acids, amino acids, nitrogen, and other decomposition by-products for estimating time since death. All have shown some potential as indictors for TSD over extended postmortem periods. A recently emerging area of interest in decomposition chemistry is the analysis of volatile organic compounds (VOCs) or the scent of death as it is colloquially referred to. These scent molecules can be collected from the soil surrounding the remains (Perrault et al. 2014), from clothing (Nizio et al. 2017), or from the headspace above the remains (Dekeirsschieter et al. 2012) and are used to class the different stages of decomposition that can then be related to TSD.

However, in the field of archaeology, methods based on soft tissue analysis are rarely useful as only skeletal elements are typically recovered. The majority of research in this area has thus focused on improving the methods used for dating anthropological skeletal remains. A range of morphological, chemical, immunological, and radiological studies have been conducted over the past century (Forbes and Nugent 2016). Morphological studies investigated physical characteristics such as bone density, specific gravity, and weight, while the chemical and immunological studies focused on organic components of bone, bone extracts, and bone diagenesis. The major challenge in all of these studies was an inability to account for the effect of taphonomic processes on bone degradation.

One of the more promising areas of investigation has been the use of radioactive isotopes to date archaeological and forensic bone samples. Radiocarbon (^{14}C) dating is commonly employed for dating historical and archaeological material, including human and animal remains. More recently, radiocarbon dating with reference to the modern bomb curve has been employed to determine the date of birth and death of recently skeletonized human remains (Ubelaker et al. 2006). The method uses the "bomb pulse" produced in the atmosphere between 1950 and 1963 as a result of extensive nuclear weapons testing. The temporal decay of radiocarbon in cortical and trabecular bone has been successfully employed on adults of known birth and death dates, demonstrating the value of this method for estimating time since death of forensically relevant skeletal remains (Ubelaker et al. 2006, 2015).

Tiwanaku, Geography and Culture of

Jédu Sagárnaga
Universidad Mayor de San Andrés (UMSA), La Paz, Bolivia

History

The site of Tiwanaku was known by human groups that occupied the Andean Highlands after the fall of that culture to 1150 AD. The Incas understood this as a sacred place created by the gods and built myths about its creation.

The famous ruins of Tiwanaku were known to the Western world after the Spanish invasion of American territory. The chronicler Pedro Cieza de León, who visited them around 1549, was showing curiosity towards the ruins and to know who had left them, assuming that they had been the Incas, something that the natives were quick to deny (Cieza s/d: 458).

After Cieza many other Spaniards referred to Tiwanaku in their writings. To 1605 frier

Reginaldo de Lizárraga writes that "almost no curious man goes through the Desaguadero [River] who does not go to see the old buildings of carved stone of Tiwanaku" (Lizárraga 1909).

In fact, thousands of people visited Tiwanaku moved by curiosity and set in providing it with magic or extra continental origin.

These strange ideas multiplied even during the Republican era (of Bolivia). The US diplomat George Squier, for example, found kinship between Tiwanaku and the distant ruins of Baalbec, and Stonehenge (Squier 1974: 147–162).

During the nineteenth century, travelers came to Tiwanaku of very different trades, such as Artists, geologists, naturalists, diplomats that could not avoid drawing, describing, and in some cases, interpreting the ancient ruins.

Several of these travelers formed important archaeological collections that they took to their countries of origin. Among these explorers, figures like d'Orbigny, Rugendas, Castelnau, Tschudi, Markham, Squier, Mitre, Wiener, Ber, Nadaillac, Middendorf, and several others stand out (Ponce 1995). Unfortunately, many were limited to interpreting Tiwanaku based on the stone buildings, nothing else. This led them to think that Tiwanaku was only a Ceremonial Center (e.g., Squier 1974). That idea was kept by Bennett (1956), Alden Mason, and several other researchers, particularly Americans, well into the twentieth century (Figs. 1, 2, 3, 4, 5, 6, 7, 8, 9, and 10).

But turning back, it is convenient to refer to the expedition that starred French Alcides d'Orbigny, who in 1833 spent 2 days in Tiwanaku. He recognized three monuments: Kalasasaya, Akapana, and Pumapunku. At that moment, Kalasasaya was partially covered by earth, from which only the stone pillars protruded, which we now know kept the smaller ashlars. He drew Pumapunku floor plan and believed this building to be the Council room. He concentrated his efforts towards describing the sculpture which is known as the "Gateway of the Sun" which at the time was dropped and split into two, pointing out that it is observed "an all-powerful King whose two scepters that symbolize both religious and political power." He thought he saw in that character, the representation of the Sun, whose worship belongs, instead to the Incas, although he thought that Tiwanaku "is indeed the cradle of the civilization of the Incas and the cult of the Sun" (D'Orbigny 2002: 1682). Perhaps it is due to that this door frame is called "of the Sun."

For this researcher, "the first religious and monarchical Government was born in the heart of this society" (D'Orbigny 2002: 1688).

Tiwanaku, Geography and Culture of, Fig. 1 Conservation at Akapana Pyramid

Tiwanaku, Geography and Culture of, Fig. 2 Restored Kalasasaya

Tiwanaku, Geography and Culture of, Fig. 3 Restored semi subterranean Temple

At the same time have other, almost anecdotal writings, such as that of Francisco de la Porte, count of Castelnau, who was in Tiwanaku up to 1845. Like most men from his time, this Frenchman believed that the civilization that built Tiwanaku disappeared without a trace and it had nothing to do with the "stupid race inhabiting this country today" (Sagárnaga 2003: 294).

George Squier was a US diplomat whose professional work brought him to South America in 1863. In June of 1864, he stayed a week in Tiwanaku. In his writings, he called it "The Baalbec from the new world" and believed it to be a "uninhabited ceremonial center," in other words "a shrine or sacred place, whose position was determined, by a wish or a dream." His

Tiwanaku, Geography and Culture of, Fig. 4 Conservation at Kantatayita

statements, as we shall see, found echo in other North American researchers like Bennett and Mason but were later refuted by Lanning, Ponce, Browman, and researchers of the Wilajawira Project.

Between the end of nineteenth century and the first third of the twentieth century, four personalities stand out in the investigation referred to Tiwanaku. Ponce called them "pioneers archaeologists" (Ponce 1995).

The German Max Uhle (1856–1944) was one of the most prominent pioneers. Even before knowing Tiwanaku, he wrote a thick volume that was co-authored with Stubel (Stübel and Uhle 1892). In this book called *Akapana to Kalasasaya*, confusing both buildings. Anyway, and this is apparent, he notes that toponymy is not old, but actually recent. Noting that Kalasasaya seemed only an alignment of standing stones, noticing the similarity with Stonehenge in Salisbury (England). He was wrong, as we will see later. He attributed it the function of temple.

Speaking of Akapana, he thought that it was a simple natural Hill. In this assumption, he committed an error of interpretation. He tersely speaks about Pumapunku, pointing out that it is a natural Hill, cut in such a way that served as the basis for another old building.

Tiwanaku, Geography and Culture of, Fig. 5 Sculpture of Pukara style, founded in Tiwanaku

Tiwanaku, Geography and Culture of, Fig. 8 Polychrome textile, from Pulacayo

Tiwanaku, Geography and Culture of, Fig. 7 Classic clay jar, from Pariti

All that Uhle wrote, he did so without having never visited Tiwanaku. Just 2 years later, in April 1894, and due to the criticism of contemporary researchers, he arrives at Tiwanaku and remains in Bolivia 2 years researching this and other sites (Ponce 1995).

Then another scholar, Posnansky, had published a guide to Tiwanaku, which Uhle criticized gaining an enemy with whom he argued with at great length. Uhle surmised that the roots of Tiwanaku were in the ancient Maya empire, something that today has no support. He also said that Tiwanaku had a single time period, and it unfolded between 500 and 800 of our time. In any case, he said that a culture was pre-Inca. He thought that the Tiwanaku culture spoke aymaran, notion that several scholars agreed with, including Ponce. He correctly pointed out that Tiwanaku had expanded to the Pacific coast. In one of his writings mentioned the "ancient Tiwanaku Empire" (Ponce 1995).

As it was the "fashion" at the time, Uhle brought back to Germany an important archaeological collection, which meant a significant loss of cultural heritage for Bolivia.

For his part, Adolph Bandelier (1840–1914), of Swiss birth and American citizen, was an empirical archaeologist. He came to Bolivia in an effort to study the pre-Hispanic culture. From 29 August 1894, he was in Tiwanaku 19 days, limiting himself to make a reconnaissance of the ruins of Tiwanaku. A Government provision forbade him to execute archaeological excavations there as he intended. It proceeded, then, to collect archaeological objects acquiring them by stealing them from farmers at night, according to his own confessions.

Tiwanaku, Geography and Culture of, Fig. 9 Copper-arsenic cramps to join large stone blocks (Museum of Tiwanaku)

Tiwanaku, Geography and Culture of, Fig. 10 Basketry from Pulacayo

Then he did an about-turn and went to the Copacabana peninsula and the Lake Titicaca islands, where he stayed 5 months in 1895 carrying out research and archaeological excavations (Sagárnaga 2013).

Bandelier argued that Tiwanaku was an ancient human settlement, a village where dwelt a "tribe." The "Tribal" perception was inherited from his teacher Lewis Morgan (Sagárnaga 2013). He also said that it housed about 6000 inhabitants, although not indications about how he made his calculations were recorded.

Among the more important monuments in Tiwanaku, Akapana clearly stood out. He considered it – same as Uhle – a natural eminence. Also he considered Pumapunku as a hill, a mistaken appreciation. He is the first author who mentions the name "Kalasasaya," although somewhat wrong in his spelling designates it "Kalisasaya." Does not support names that was popularly attached then, as the Court of Justice, strength, etc. He drew a site plan from the ruins, which he left unreleased and unaccounted for.

Possibly his most important contribution is to have identified that the area was divided into two.

He thought, moreover, that this dualistic organization could be traced back to pre-Hispanic periods and that it could have lasted until now, which is later evidenced more clearly (Sagárnaga 2008).

The third pioneer to which we will refer was the Swedish Erland Nordenskiöld (1877–1932), who conducted six expeditions to American lands. During the third of which (1904–1905) he probably visited Tiwanaku. The greatest merit of this researcher consists in having recovered evidence of the expansion of the Tiwanaku culture, both towards the North in Keara (canton Pelechuco) to more than 200 km and towards the Southeast in Mizque, Caballero, and Saipina, of the states of Cochabamba and Santa Cruz, to more than 390 km outside the capital of that social formation.

The fourth character of this group is Arthur Posnansky (1873–1946). Born in Austria, he became a Bolivian national, he lived until his last days in the Andean country and devoted his life to the study of Tiwanaku. He was a naval engineer and became a self-taught archaeologist.

He conceptualized Tiwanaku as a cultural seed for America based on the diffusion of the staggered sign as a religious symbol. It also believed that Tiwanaku was a Lake port; that there existed a class division based on caste: the superior caste (kolla) and the lower caste (arawak); and that its age was between 10 and 13,000. He also established a sequence of three periods for the Tiwanaku culture. He also pointed out that the tiwanaku had knowledge of accurate calendars. Although many of his theories have already been refuted, science should not only thank him for the valuable drawings that he left us but also for having taken the first steps in the systematic study of our pre-Columbian past and have it disseminated as few have before him (Sagárnaga 2003).

Following the sequence proposed by Ponce Sanginés (Ponce 1995), this stage is followed by what he would call "excavators in small scale and collectors."

Before anything else, we must refer to the French scientific mission G. de Créqui-Montfort and E. Sénéchal de la Grange. Between its members you find the geologist Georges Courty who, in an almost casual way, excavated in Tiwanaku between 1903 and 1904, taking to France a significant archaeological collection which caused a formal complaint from the Bolivian Government. Among the publications of the mission which were announced, you find the article "Fouilles archéologiques to Tiwanaku" by Courty and Mortillet. However, for reasons that are unknown, it was never printed (Ponce 1995). It is likely that it had never been drafted. Also Courty's field notes were lost and the only thing that was published was a short article whose author is Créqui-Montfort.

According to Ponce, the work that the French made was deplorable and even devastating, as evidenced by the serious damage that was caused to the "cabezas clavas" (ornaments) encased in the walls of the small semi subterranean Temple, chipping them without any consideration. The Brooklyn Museum has published 61 photographs from photographer Sintich resident in La Paz and hired by the Mission (http://www.brooklynmuseum.org/opencollection/archives/mission_scientifique_fran%C3%A7aise_en_am%C3%A9rique_du_sud__travaux_et_fouilles_de_tiahuanaco_1903). It is the most important document which remains of the French intervention in Tiwanaku.

The first thing done was to open a trench from the north to the south transversal to the Akapana pyramid from the visible base. He found parts of a Grand canal. From the photographs, it can be established that they were deficient excavations.

Close to the railway line which goes to Guaqui, a collapsed stone stele was coincidentally found. Digging there, two other steles were found. Which were probably inside an enclosure that was not clearly visible.

Ponce then inferred from these photographs (Ponce 1995) that Courty excavated the small semi-subterranean Temple, which by then was covered by sediment. He dug a trench along the four retaining walls. It seems that his sole purpose was to extract the cabezas clavas which were embedded in the walls, and did not have the care needed to maintain the structural integrity of these walls. Luckily, due to lack of time, he did not dig inside this small temple.

With regard to Kalasasaya, he discovered the main access stairway of towards the East and he excavated partially using a trench. It is also inferred that he practiced more excavations in another building of Tiwanaku: Putuni. Through the pictures, we can infer that after the excavations of Courty, a noticeable amount of vandalism occurred, probably from the local population, which caused great destruction, given to the fact that today the structures, whose images were a unique witness of their former existence, no longer exist.

Without any real evidence, Courty proposed a Mayan origin to Tiwanaku (Ponce 1995), most likely agreeing with Uhle. He also had no scientific basis for the comparison he did between Kalasasaya and the Crucuno Dolmen (in France).

Guaqui – La Paz (1902–1903) railroad construction made the ruins into a quarry, which contributed to an even greater material degradation of the remains of Tiwanaku. The intellectuals of the era, such as Camacho, protested against such acts.

The Bolivian Belisario Díaz Romero (1870–1940) was a physician by profession and one of the main exponents of the Darwinian current in Bolivia, visited Tiwanaku towards 1897, and dared to say that it had been founded as a colony by White men and Aryan lineage from the enigmatic Atlantis (Ponce 1995). His writings only have anecdotal value.

The Congress of Americanists in Buenos Aires was held in 1910. Attendees received an invitation from the Bolivian Government to visit Tiwanaku. Thus, a group of scholars were cited in the ruins. Among them was the Argentinian Salvador Debenedetti, German Max Uhle, Lehmann-Nitsche, Posnansky, the outstanding intellectual Manuel Vicente Ballivián, and several others, including former President José Manuel Pando. It is known that Max Uhle, who had visited Tiwanaku 16 years ago, was upset by the ruins that were in worse condition. In any case Debenedetti biographers have pointed out that of all the South American cultures of the Andes, the one which attracted his spirit the most was that of Tiwanaku. Surely its ruins excited him.

Continuing with the story, Julius Nestler, Professor at a high school in Prague, was also interested in Tiwanaku and got assigned as the Austro-Hungarian consul in Bolivia. In this country he amassed a collection of 3644 specimens, most from Tiwanaku, which are now exhibited in Prague in the Naprstek Museum.

Among the things that archaeologists would like to forget are excavations of Otto Buchtien, who was hired by the Bolivian Government as Director of the National Museum and whose specialty was Botany. Without any knowledge of archaeology, he decided to dig in Tiwanaku in 1913 for a period of 8 weeks, his intervention resulted direr than Courty's excavation, because less data are available from this excavation. Among them is featuring a report signed by M.V. Ballivián, then director of the office of statistics and geographical studies, where it is written: "the archeological section's collection has grown thanks to the excavations realized by the director and Assistant to the Museum, which were done in the ruins of Tiwanaku, with specific instructions to carry out such works. Funds have been provided by the Ministry of public instruction and agriculture. The results of the excavations to which we have referred, have been the most satisfying, many hundreds of perfectly preserved pieces of pottery have been found; numerous skulls, bone tools and objects made of stone have been extracted. With these quotas the National Museum currently owns a complete collection and can be considered as the most notable of the world" (Ponce 1995).

Unfortunately, is not written who did the excavations or where they were done during the 8 weeks it lasted, though you can guess is that it was in the vicinity of the current cemetery.

Otto von Buchwald in his article published in Quito in 1918 defended the position that Tiwanaku was an empire consisting of the aymaras and that if you observed its remains "it is understood that only a strong and solid monarchy could have produced similar advances." It also advocated the origin of the inkas was in Tiwanaku (Ponce 1995). So in these few lines we can see three elements of discussion: was Tiwanaku an Empire? Was it composed by the

aymaras? Did Tiwanaku give origin to the Incas? Will address these questions one at a time.

The Bolivian José María Camacho was a lawyer, political leader of the liberal party, landowner, and historian (Ponce 1995). Apparently he was the first to refer to Kantatayita, which in his opinion was just a quadrangular enclosure. Curiously not mentioned was the lintel which was in the center of the area and whose image was already published by Squier.

With respect to Kalasasaya, he rejects the role of temple, but he was inclined to believe that the wall structure was formed by pillars under the guise of buttresses and by dry blocks in even intervals. He is most successful in his appreciation of Akapana, which was defined as an artificial mound, with a succession of terraces that were made at different heights with their own retaining walls. In terms of Pumapunku, it was judged that it could be a temple or Palace of Justice, with regards to Putuni, noting that the entrance was a staircase of only three steps, aiming to "rebuilding it wouldn't be impossible work for patient and knowledgeable observers." In relation to the small semi-subterranean temple, his opinion is completely wrong because thought that it housed galleries. Lastly, he saw Tiwanaku as a "sacred capital" (Ponce 1995).

Although in 1838 a public museum was created in La Paz under the leadership of the Bishop from La Paz José Manuel Indaburu, it was in 1919 that it was authorized under Executive power to rent the building known as the "Tiwanaku Palace" which was owned by Arthur Posnansky, from whom the building was bought, and Posnansky was appointed as the first Director.

Various personalities followed in office, among them Maks Portugal Zamora who made important contribution to Bolivian archaeology.

We arrive to 1932, and we have a unique character. Wendell Clark Bennett (1905–1953) was the most serious exponent in the first half of the twentieth century to try and trace a cultural sequence based on the ceramic pieces from Tiwanaku. In 1927 he receives his title from the University of Chicago and he obtained his master's degree in 1929 and his Ph.D. in 1930. He accepted a position at the American Museum of Natural History in New York in 1932 to head the department of Andean archaeology and remained in office until 1938. Then he moved to the University of Madison as an associate professor of anthropology. In 1940 he entered Yale University, also as associate professor, he was named professor in 1945 and became head of the Department of Archaeology in 1949, where he remained until his death in an unfortunate accident.

That year (1932), Bennett approached the Bolivian High Plateau and from June 15 to July 10 he undertook small scale excavations in Tiwanaku. He was authorized to realize 16 units of excavation each of which had to be 10 m^2. Actually he carried out only a dozen of these excavations, whose total area reached 120 m^2. It was agreed that valuable exhumed objects would then be handed over to the National Museum, but that duplicates would be taken by him in his capacity as member of the American Museum to which he belonged, something that was inconvenient for Bolivia. A Supreme resolution was issued in July of 1932, by which it was authorized to export archaeological findings on loan for a year to the Museum where Bennett worked, only referring to the relevant inventory. The return was never carried out and Bennett broke this agreement.

The methodology adopted for small-scale excavation by Bennett in Tiwanaku followed the imposed criteria of arbitrary levels, each 0.5 m deep and not subject to natural stratification or separation of the sediments by individual layers. These arbitrarily thick levels obviously cut more than one stratum and materials of different stages in the cultural succession were then mixed together which led to a state of confusion; it can be said that this did not allow a more refined identification of the pieces.

Bennett proceeded to the open 10 units of excavation or pits as he called them, whose main characteristics are resumed here. The first is located at 420.3 m from the railway station and following the Railroad, next to the modern cemetery of Tiwanaku, with an area of 5 × 2 m, and a depth of 2.50 m, and he discovered a layer of ash and coal that corresponded to a stratum that is normally found at a depth of 1.50 m. The second,

on the embankment of Kalasasaya, 38 m from the southwest corner, with an area of 3.3 × 3 m, with a maximum depth of 3.50 m. Their field observations were inadequate, since he found some rubble belonging to a building at the top, as well as having located the high stratum of the embankment, but he failed to interpret it. If he had dug more carefully, he would have discovered the strata corresponding to I and II eras of Tiwanaku (described by Ponce), an inexcusable omission. The third was excavated 245 m Northwest of Kalasasaya, with an area of 3 × 3.30 m, which finished with a depth of 1 m. He did not publish the case section. The fourth is located almost opposite to the first, separated by the railway, 15 m from it, with an area 3 × 3.30 m, which reached a depth of 3 m. It can be deduced that at 1 m he found traces of the Foundation of a building. The fifth pit is located near Kantatayita and 126 m east of Akapana, with an area of 3 × 3.3 m and a depth of 4.5 m. He found at least two locations, with remains of some buildings and almost at the bottom a floor with domestic remains. Pit 6 East of Pumapunku produced no significant results. The seventh pit was opened in the small semi-subterranean temple and resulted in the discovery of the 10th Stela, where it became necessary to expand the excavation to an area of 4 × 2.5 m in order to fully reveal the wonderful sculpture, a certainly sensational finding and that was subsequently appointed the Bennett monolith, in homage to the archaeologist. The aforementioned researcher confused the filling of the temple with its date of construction, as it was later determined by the excavation carried out by Tiwanaku Archaeological Research Center on the precise spot that was just mentioned, as well as the stele whose main face is aimed towards the south, towards Akapana. The 8th pit is located south of Putuni and 112.7 m southwest of the southwest corner of balcony wall or Chunchukala of Kalasasaya. There was a foundation of wall that Bennett assumed was a channel, with two parallel stone blocks but devoid of a background, associated with an occupational layer that had abundant pottery, with an area of 3 × 3.3 m and a depth of 2.50 m. Below, it is likely that there were domestic remains. The ninth pit is located next to the train station and the tenth in the modern cemetery, but neither offered new information (Bennett 1956).

As noteworthy results, it can be mentioned that Bennett obtained approximately 14,500 fragments in their excavations, of which 69.78% were smooth pots, 22.24% were painted, and the remaining 7.98% were miscellaneous, with noticeable predominance of functional pottery. As far as ceramic morphology is concerned, he stressed the preponderance of five forms, two of them unrestricted – the cup and the Bowl – the censer with annular base and double-sided handle, the basin, and a vase with an ovoid body and a neck. He established a cultural sequence with three epochs: ancient, classical, and in decay. He pointed out that the difference between the classic and decadent was only stylistic.

Bennett led the explanation that Tiwanaku was just a ceremonial center, controlled by a powerful religious organization. That was built at intervals and not in a continuous fashion, and many of the buildings were never completed. In his view, it was primarily composed by four major architectural structural units: Akapana, Kalasasaya, Pumapunku, and Putuni. He thought that it welcomed pilgrimages, with human masses who flocked in certain seasons of the year to contribute with offerings of work or by transporting building materials. The art, he considered symbolic and formal. Bennett only managed to distinguish the visible buildings and not the adobe buildings underground, covering a much larger expansion. Neither could he understand the urban layout that had a residential portion. His statement about the expansion thanks to the indoctrination of religious missionaries would have an impact in the sense that the phenomenon would be reflected in intrusive cultural elements from another culture and not to justify cultural uniformity that prevailed. To Ponce, his vision of Tiwanaku is too narrow (Ponce 1995).

With successes and failures certainly Bennett, in a fair balance, did advance scientific knowledge of Tiwanaku.

The Argentinian Eduardo Casanova came to Tiwanaku in 1933. It is known that his intervention in the ruins was due to an invitation that Posnansky extended so that an Argentinian

mission could study them. Casanova was not adjusted to any plan and dug anywhere by opening about 25 pits of approximately 2 m^2, without any real order. His eagerness was simply to obtain artifacts. He found layers of ash 5–20 cm thick, the more superficial to 80 cm, and the deepest up to 4 m, which can be understood as a byproduct of human activity, although he did not know how to interpret them. He also discovered underground drainage canals on the embankment of Kalasasaya, which later had to be destroyed by the vandal activity that occurred there. Referring to Akapana, called it "pukara," i.e., fortress. Big mistake, as a fortress in the middle of the city is inconceivable (Ponce 1995).

Unfortunately, it has only three short articles of Casanova and not a serious publication about his excavations. Therefore, little is known about its intervention in Tiwanaku.

About Fritz Buck (1877–1961) it is known he was a German immigrant who took up residence in La Paz. He was in Tiwanaku, for the first time in 1908, and 4 years later installed a jewelry store in the seat of power of Bolivia. Although economic activity was jewelry, he became a tireless collector of archaeological artifacts, activity that was his passion. He even had a small house built close to the ruins where he apparently carried out the purchase of antiques from the surrounding farmers, who discovered all kinds of objects in their lands. Around 1930 he left his jewelry store in the hands of her brother-in-law to devote himself completely to his work of collector. He came to assemble a collection that later comes in to 3834 specimens of pottery, metal, stone, and organic origin. The majority of which came from Tiwanaku, but also objects from other parts of Bolivia, even some from Peru and other neighboring countries. Despite everything, his inventory is rather incomplete and it has almost no accurate source of the pieces. He only wrote a handful of newspaper articles lacking scientific rigor, and therefore of little use. Only in 1937 does he write his first and only book *The Mayan Calendar in the Tiahuanacu Culture*, based on the symbology of the Tiwanaku art that was registered in different types of media, as well as complex astronomical calculations. Despite this, and despite the analogies between the Andean and Mesoamerican cultures, it cannot be concluded that the Mayan culture had any influence on the culture of Tiwanaku. The Buck collection is preserved today at the Museum of pre-Columbian Precious Metals from the city of La Paz (Sagárnaga 1987).

It is advisable to refer to Stig Rydén (1908–1965), disciple of Nordenskiöld, who also practiced in Tiwanaku small-scale excavations in 1938 where he made the opening of seven boreholes covering a total area of just 22.41 m^2. The defect of the excavation by Rydén consisted on using arbitrary levels of 50 and up to 75 cm in thickness, which was too thick. He established the existence of three different types of ceramic based on the finish and in its function: a rough ceramic for cooking food, another for the storage of liquids, and one that was artistically made for ceremonial purposes. After the Second World War, Rydén would publish his thick volume titled "Archaeological Researches in the Highlands of Bolivia" (Ponce 1995). Ponce, who was very hard in his opinions regarding the actions of certain researchers, was softer when it came to Rydén, probably because they had established a close friendship, in 1951 they dug together in Mollo. Either way, it is important to note that Nordenskiöld took a collection of 3.390 artifacts from Bolivia to Sweden, his disciple – Rydén – overtaking him, who took 11.760 objects from the same country (Muñoz 2012).

Another collector, certainly more noteworthy than Buck, was Federico Diez de Medina (1882–1963), true lover of pre-Hispanic art. He wrote a dozen archaeological newspaper articles between 1942 and 1953. He maintained a friendly relationship with Posnansky who led the Archaeological Society of Bolivia and who influenced his vision of Tiwanaku, only difference being that Diez de Medina exaggerated saying not only that Tiwanaku was a port, but a port of the Atlantic Ocean and with a direct connection with Atlantis. Also that Tiwanaku was up to 18,000 years old. He also speaks of large earthquakes and volcanoes forming following a catastrophic event, all of this was discarded by geology. But he had the good sense to identify the use of trophy-heads in Tiwanaku (Ponce 1995).

He accumulated one of the most important archaeological collections in Bolivia, later acquired by the Bolivian State, which today is located in premises of the National Museum of archaeology, in La Paz. Subsequent to his death, the cataloging of this collection brings the figure to 18.662 specimens including non-pre-Hispanic objects. (Sagárnaga 2003).

Alfred Kidder II (1911–1984) came to Peru and Bolivia for the first time in 1937. He returned to Bolivia in 1955 and in Tiwanaku dug a couple of Stratigraphic pits, with a total area of 20 m^2. Kidder published only one article in a newspaper detailing his mission in Bolivia, and it was Gregory lamb Miranda, in his capacity as Assistant Director of the Tiwanaku Museum, who came to supervise the work of the North American and write a 4-page report regarding his activities. Thanks to this, it is known that Kidder's work was deplorable because he failed to disperse layers or to interpret the stratigraphic sequence (Ponce 1995). Kidder places Tiwanaku at the stage of builders of cities, which is located between the 600 and 1000 AD, sustaining that in Tiwanaku, there emerged a powerful force joined to a religious cult with emerging military leadership.

Another curious character was Ruben Vela, poet and Argentine diplomat, first Secretary of the Embassy of his country in La Paz to 1955. He formed almost surreptitiously and quietly a collection of approximately 928 pre-Hispanic items from Bolivia which, conspicuously, was later donated to the Service of Prehistoric Research of the provincial Council of Valencia (Spain) (Ponce 1995). He not only looted Bolivia's assets but acted in a servile manner by donating the collection to Spain.

The 1952 National Revolution of Bolivia sought to restore rights which had been stripped from the indigenous almost since the Spanish conquest. It also laid the Foundation for the search on ancestral roots. It was necessary to bring together scholars from the past who worked in the national territory so that at the end of 1953 was held the first Roundtable of Bolivian Archeology in order to assess the State of the situation and set goals from there onwards (Ponce 1995).

All this constituted the propitious scenario that in 1957 started the archaeological excavations at Tiwanaku under the direction of the Bolivian Carlos Ponce Sanginés. The following year the Centre for Archaeological Researches in Tiwanaku is officially created. This event was a milestone in the research on Tiwanaku which used to be the privilege of foreigners who stayed for short periods in the country until then. The first report of work was published in 1961 (Ponce 1961). The institutionalization of the Bolivian archaeology supported by State action arose; this spread to other points of archaeological interest in the Bolivian territory, which enabled the creation of the National Institute of Archaeology (INAR) in 1975.

Among the most important achievements of the INAR the intense field work, the hundreds of surveys, verification of systematic excavations, defense of the cultural heritage, stopping the illegal export of items, adequate equipment, construction of museums, preservation of sites, etc., should all be noted.

Among the measures of protection that were taken is the placement of a mesh fence around the two most important sectors of Tiwanaku (the Akapana and Pumapunku), covering about 34 ha, the cataloging with scientific basis of archaeological artifacts (until 1980 it had listed 45.870 objects, belonging to the National Museums of Archaeology of Aukapata, of pre-Columbian precious metals, of Copacabana, of Samaipata, of ethnography, the Medina and Buck collections (and other smaller collections); excavations were carried out on a large scale (in Kalasasaya, in the small semi-subterranean temple, Kherikala, Lakkakollu, a portion of Putuni the eastern side of Akapana and the south-east corner of Pumapunku); the Kalasasaya and the small semi-subterranean temple buildings have been restored. In 1989, Carlos Urquizo, director of the INAR, resumed excavations at Pumapunku with the participations of Juan Faldín, Sonia Alconini, Max Portugal, Oswaldo Rivera, Javier Escalante, Leocadio Tic. . .

Ponce Sanginés established a cultural sequence in three stages of development: villager (epochs I and II), urban (epochs III and IV), and Imperial (epoch V).

The villager, the economy was based on self-sufficient agriculture of Andean plants. There was no distinction of social classes. The dead were buried in holes in a kneeling position. Copper was already being smelted. We found an artistic ceramic called "Kalasasaya," associated with a rough micaceous polish (Ponce 1995).

The urban phase, according to Ponce, is divided into early and late. The city and state appear in the early urban phase. At the same moment we have the division of society into social classes. The surplus of production sustains the State apparatus. The big buildings that have remained to the present day are constructed: the Akapana pyramid, Kalasasaya, and Pumapunku. An urban planning with dualistic conception in two halves is concluded. Polychrome ceramics are produced, with feline like paintings and geometric pottery. Both the architecture and sculptures used the red sandstone as a raw material. This stone comes from nearby quarries in the mountainous South.

The late urban stage, characterized by the beautification of buildings, use of andesite as lithic material which was much finer than sandstone and was transported from the peninsula of Copacabana. As for metallurgy, copper alloys with arsenic were developed. Ceramics production reaches an exceptional quality; hence, it is known as "classic." Also the stone sculptures reached a high degree of perfection. An expansion of the Tiwanaku model begins.

In the third and final phase, there was an expansion on a vast scale. Tiwanaku became the imperial or Pan-Andean Universal State with a vast subject territory. Ponce estimated that the population of the city was 100,000 inhabitants. Bronze is discovered. The pottery quality drops. At the end of the twelfth century of our era, the Tiwanaku Empire entered its decline, apparently for climatic reasons which led to drought with the consequent decrease of crops and increase of the political crisis. The regional estates then appear (Ponce 1995).

Sixty-three radiocarbon dates were obtained with the following averages: 237 BC to the period I, 43 AD II, 299 AD for III, 667 for the IV, and 1050 for the V. The oldest date obtained gave 1680 BC and, most recently, 1172 AD.

The city reached an area of 420 ha and was divided into two halves. The buildings obey a rigorous astronomical orientation according to the cardinal points were a network of roads would come out in various directions.

Ponce called "Integrator" model to that which was imposed in Tiwanaku, because – according to him – various ecological floors were integrated as well as the highland areas from north to south.

From 1988 a joint project between the National Institute of Archaeology and the University of Chicago was held. The "international seminar of archaeological excavations in Tiwanaku" (1988–1989), co-directed by Carlos Ponce and Alan Kolata at the University of Chicago, led new excavations to Akapana (1988–1989). The work was entrusted to Linda Manzanilla (Mexican) and María René Baudoin (Bolivian). Thanks to them, different retaining walls within a tiered system that set up the pyramid were identified. On the second terrace a gigantic offering of intentionally cracked ceramic was discovered, as well as dismembered human skeletons. Atop the socket containing a housing complex with rectangular rooms and two spacious rooms was excavated. Another remarkable finding was that of a sculpture of blackish rock representing a man with mask of feline, a Tiwanaku piece which is known as "chachapuma."

Escalante excavated an area of 228 m^2 on the site called Lakkaraña (1990–1991). He discovered a retaining wall, a circular structure, and the foundations of a rectangular House as well as a tiny anthropomorphic figure made of copper.

On March 23, 1990, an agreement was signed between Oswaldo Rivera, Director of the National Institute of archaeology of Bolivia and Kolata by the University of Chicago, to carry forward the Wilajawira Project, which provided "comprehensive research and analysis of the pre-Columbian cities" Lukurmata, Pajchiri, Wankani, and Tiwanaku, a multidisciplinary team, with emphasis on the study of pre-Hispanic agriculture and its relationship with the tiwanaku State. Field work included two seasons during 1990 and 1991.

Between 2004 and 2008, and under the command of the National Unit of Archaeology (which had changed its name from National Institute of

Archaeology), Javier Escalante – understanding institutional boom era was that of Ponce – pretended to re-edit the efforts of this archaeologist undertaking four archaeological projects and that had to do with Akapana, Pumapunku, Putuni, and Kantatayita. In the project of Akapana became clear most of the N and W of the stepped structure flank walls. Pumapunku became work of monumental blocks leveling and S walls and part of the W freed themselves from their coverage. Putuni carried out excavations and conservation on the S and W walls work; and finally, next to the polish-italian mission excavations at Kantatayita were started for their respective work of conservation (Escalante 2012: 265).

At the present time, research being developed around Tiwanaku is scarce.

A Particular Vision of Tiwanaku

The word Tiwanaku has two meanings: on the one hand it refers to the pre-Columbian town located 71 km from the current seat of the Bolivian Government. On the other hand, it refers to the Social Formation whose center of primitive cultural irradiation was mentioned, which expanded all over the western part of Bolivia, the South of Peru, and Northern Chile and Argentina.

The phase that Ponce called villager, in the light of current evidence, would seem that it was part of a much more extensive process in the northern highlands and which Chiripa in the southern basin of Lake Titicaca and Qaluyo, in the North region, were also part of. This certain stylistic unity was promoted, probably, by a common religious substrate.

In the same way that the Tiwanaku phenomenon had its background in an early formative horizon, you also have another cultural expression that was also developed in the northern basin during the Middle formative period, which is known as Pukara. But itself Tiwanaku as such would begin just to the first century of the era, during which Ponce called early-urban. If there were a village, as it seems to have been proven, it is turned to city with the construction of buildings on the basis of lithic material (the red sandstone), the establishment of an elite caste administrating surplus production, a middle class composed of specialists (sculptors, potters, weavers, metallurgists, etc.), and around the city, a mass of peasants engaged in farming. The anthropomorphic sculpture does not have even the level of preciousness reached in the subsequent time (urban late or classic) but is a precedent. The morphological history of pottery (known as Qeya) is clear; this determines some of the forms of corporate Tiwanaku ceramics, just as censers of wavy edges characterized the classical Tiwanaku ceramics, so do the kerus. Janusek called it late formative period, but the above can be considered as an initial Tiwanaku. In this sense, and rather casually, Bennett would have been successful with the cultural sequence of three times that proposed to Tiwanaku: early (epoch III in the sequence of Ponce), classic (IV of Ponce), and decadent (Imperial or Ponce V).

The classical period meant the heyday of High Plateau culture in the political, economic, and religious aspects which are expressed in the material culture that can be studied. Their cultural expressions were very peculiar. They developed a monumental architecture, a very elaborate sculpture, very fine ceramics, a highly advanced state of metallurgy, and other aesthetic and technological indicators that show a very complex social formation.

In its final stage, its expansion was admirably large. Territorially, it expanded by Sierra and south coast of the Peru from Chile, from Argentina and the Highlands and valleys of Bolivia.

It seems that the fine ceramics that characterized the previous time continued to produce at this stage, but probably for the exclusive use of the ruling class or the nuclear area, while less fine ceramics – which are known as expansive – was the most popular and was sent to the farthest edges of the empire.

Its development is parallel with the Ayacucho village: Wari who unfolded synchronously to the Tiwanaku and had its area of influence the north of them. In the light of current research, it is said that Wari was an Empire (the first of the Andes) and Tiwanaku was not so. If we define "Empire" as a social formation that conquered and absorbed

unprecedented social formations, and to exert political and political control above a vast territorial expansion, also Tiwanaku was imposed on other people and spread in an area of 600,000 km^2, according to calculation of Ponce. On the other hand, there is an unfortunate imbalance in the investigation that is underway around Wari (in Peru) and which is made around Tiwanaku (in Bolivia), favorable to the most northern culture. Be that as it may, Tiwanaku was a powerful State of the Middle Horizon.

The city of Tiwanaku, whose ruins are the most important of the Bolivian territory, is 16 km from the banks of Titicaca by the West and just 12 in the North. It occupied an area of 240 ha. and it had a population of at least 40,000 inhabitants, in its heyday.

The figure of 100,000 inhabitants, which was given by ponce before, seemed to be too high, and most scholars were doubted that the population reached even a quarter of said amount, because it was not clear where they could have obtained the necessary amount of crops for so many people. However, in 1979, Alan Kolata and Oswaldo Rivera reported about an extensive area of farmland located at the north of Tiwanaku. This farmland would have had an extraordinary production capacity, based on raised fields in the Pampa Koani area, whose production could have supplied even more people than what was originally estimated, although not necessarily all production served for the sustenance of Tiwanaku, any production surplus could have been used to undertake new tasks.

Tiwanaku shows a very clear urban outline and boasts advanced and unique technology. They erected a large and sumptuous buildings of stone in its ceremonial sector, such as Akapana, Kalasasaya, the small semi-subterranean Temple, Putuni, Kheriqala, Kantayita, Laka Kollu, Pumapunku, and others remaining to be discovered.

Bermann, Goldstein, Stanish, and Watanabe argue that the Tiwanaku unfolded gradually over a Millennium and that its economy was based on the spur agricultural technique, production of tubers, intense stockbreeding of camelids, the establishment of colonies, and an extensive network of Exchange, which comes in its economic and political high point towards the 900 AD.

There is new evidence that when at the end of tenth century, the Tiwanaku elite knew that the – hitherto – successful model was beginning to crumble, and they understood that this was due to a disagreement of the gods who sent his punishment. In an effort to reconcile with them, the Tiwanaku carried out a series of sacrifices. This may explain the human sacrifices that were placed on the second terrace of the Akapana pyramid, and various ceramic offerings and from animals that have been located in some sites. The discovery of Pariti, carried out in 2004 by the archaeological bolivian-finn mission and headed by Antti Korpisaari and Jédu Sagárnaga, could be explained as an offering of this type (Korpisaari and Sagárnaga 2007, Sagárnaga 2015).

In relation to the language that would have been spoken in Tiwanaku, it is very difficult to determine what it was. Uhle, Ponce, Montaño, Albarracín, and several others believed that it was the Aymara. However, every time we are more convinced of the ideas of Rodolfo Cerrón Palomino and Alfredo Torero, who proposed – each on their own – the Aymaras invaded the Tiwanaku territory contributing to his downfall, and that – rather than it happening – in the Andean Highlands, Pukina was probably spoken.

In December 2000, Tiwanaku was declared site, Natural and Cultural Heritage by the United Nations for Education, Science, and Culture Organization (UNESCO).

Tobias, Phillip V.

Peter S. Ungar
Department of Anthropology, University of Arkansas, Fayetteville, AR, USA

Basic Biographical Information

Phillip Vallentine Tobias was a South African paleoanthropologist and human biologist. He was born in Durban, South Africa, in 1925 to Joseph Newman Tobias and Fanny (née) Rosendorff. His father was a toyshop owner and his mother was a piano teacher. Tobias was fascinated by natural history from a young age. His wolf-cub scout leader introduced him to osteology and anatomy. His interests in genetics, zoology, and archaeology followed from frequent visits to the Durban Natural History Museum during his teenage years.

Tobias entered the University of the Witwatersrand (Wits) in 1942, where he earned B.Sc. and B.Sc. Honours degrees (1946, 1947), the medical degrees M.B., B.Ch. (1950), and a Ph.D. (1953) in cytogenetics under the tutelage of Joseph Gillman. He then held fellowships to continue his work at Cambridge University (1955) and various academic institutions in the United States (1956). After his return to South Africa, Tobias was mentored by Raymond Dart and was later awarded a D.Sc. degree (1967) for his research on hominin evolution. He was appointed demonstrator and instructor in histology and physiology at Wits in 1945 and subsequently served as Lecturer (1951–1952), Senior Lecturer (1953–1958), Professor and Head of the Department of Anatomy and Human Biology (1959–1990), and as Dean of the Faculty of Medicine (1980–1982). He remained active as Professor Emeritus at the university until his death on June 7, 2012.

Major Accomplishments

Tobias made many contributions to Science, with nearly 1,200 published works on topics including genetics, human evolution, anatomy, growth and development, and the history and philosophy of science. He is particularly well known for his descriptions of early hominins from Olduvai Gorge in Tanzania, especially *Paranthropus boisei*, and for co-naming *Homo habilis* with Louis Leakey and John Napier in 1964. He supervised excavations at the South African fossil hominin site of Sterkfontein for four decades beginning in 1966. Tobias also conducted fieldwork at a number of other fossil sites in southern Africa and studied human variation and cytogenetics of living people and other mammals.

Tobias also worked assiduously on the meaning and political ramifications of race and fought indefatigably against racism. He was elected President of the National Union of South African Students in 1948, the year the Nationalist Government enacted apartheid legislation to define and enforce segregation. Tobias soon after began the first anti-apartheid campaign in a South African University to keep enrollment open to all, participating in protests against these oppressive laws. His activism continued throughout the apartheid era. For example, he coauthored a formal complaint to the South African Medical Council that

brought world attention to the mishandling of the Steven Biko case. Biko, the founder of the Black Consciousness Movement, died from injuries sustained during interrogation by police. He also lobbied for repatriation from France of the remains of Saartjie Baartman, a Khoikhoi slave that had been exhibited around Europe as "the Hottentot Venus" in the early nineteenth century.

Tobias is likewise known for his efforts toward reconciliation between science and religion, particularly in the relationship between evolution and theology. He participated in two working groups organized by the Pontifical Academy that contributed to the revision by Pope John Paul II of the Church's attitude toward evolution. Tobias was in fact born into a Jewish family and served during his youth as President of the Junior Hebrew Congregation in Durban. Indeed, the young Tobias even evinced an interest in studying for the rabbinate.

Tobias received numerous accolades for his scientific and humanitarian accomplishments. These include numerous distinguished metals, prizes, awards, and honorary degrees. He was a Fellow of the Royal Society (London) and a Foreign Associate of the National Academy of Sciences of the United States and the American Philosophical Society, Commander of the Order of Merit of France, and Commander of the National Order of Merit of Italy.

Togola, Téréba

Daouda Keita
Département d'Histoire et d'Archéologie, l'Université des Sciences Sociales et de Gestion de Bamako, Bamako, Mali

Basic Biographical Information

Téréba Togola (Figs. 1 and 2), who died November 5, 2005, was a tireless advocate of Malian cultural heritage. An expert in the field, Téréba Togola distinguished himself by his thirst for knowledge and strong sense of sharing. This open spirit strongly influenced the new generation of Malian archaeologists, who still take him as a reference point in their own activities.

Born in 1948, Téréba Togola began his professional career as a primary school teacher. In 1976, he entered the Ecole Normale Supérieure of Bamako (ENSUP) where he took his first courses in archaeology, a discipline that he would follow for the remainder of his life. The thesis he completed at the end of his studies at ENSUP in 1982, entitled *Inventaire analytique des sites archéologiques du Cercle de Bougouni (Région de Sikasso)*, is testament to his commitment to archaeology. Téréba Togola subsequently worked at the Institut des Sciences Humaines (ISH), where he actively participated in numerous archaeological missions across Mali, including the Mema region. He was a member of the team that worked on a project to create an inventory of archaeological sites in the lakes region and the Inner Niger Delta (Togola and Raimbault 1991). It was here that he met Roderick J. McIntosh and Susan K. McIntosh, who integrated him into their team of archaeological researchers working in the Timbuktu region of northern Mali (1983) and at Dia (1986). In 1986, Téréba Togola was awarded a

Togola, Téréba, Fig. 1 Téréba Togola. (Photo taken during a conference)

Togola, Téréba, Fig. 2 Téréba Togola. (Photo taken at the site of the Kankou Moussa mosque in Gao)

Fulbright Scholarship (USA) (1986–1993), which enabled him to further his studies at the Department of Anthropology at Rice University, Houston, Texas, where he obtained a Master of Arts in archaeology in 1988 and a Ph.D. in Archaeology in 1993. His doctoral thesis on the theme: *Investigations of Iron Age Sites in the Mema Region (Mali)* was published posthumously (Togola 2008). On his return to Mali in 1994, Téréba Togola joined the ISH and became the head of the archaeology section. In 1998, he was appointed the Director of National Arts and Culture (DNAC) in Mali, and subsequently the head of the National Directorate of Cultural Heritage (DNPC).

Téréba Togola was an active member of the following professional organizations and associations: the Society of Africanist Archaeologists (SAFA), the West African Association of Archaeology (AOAA), and the Mande Studies Association (MANSA). He was one of the main organizers of the 11th Congress of the PanAfrican Association of Prehistory and Related Studies (PANAF) in Bamako in 2001, the proceedings of which he coedited and co-published with Klena Sanogo (Sanogo and Togola 2004).

Major Accomplishments

In this capacity as the head of the archaeology section at the ISH, Téréba Togola directed the archaeological components of the environmental impact studies in the gold mining areas of Keniéba, Sadiola, Tabakoto (Kayes region), and Kalana et Yanfolila (Sikasso region) between 1994 and 1997. In 1995, archaeological research carried out under his supervision in the Boucle du Baoulé region revealed the richness and the diversity of archaeological sites in the National Park of the Boucle du Baoulé. Téréba Togola also took an active part in initiating and implementing an archaeological research program in the southwest region of Gourma, directed by Kevin MacDonald (1993–1996). Funded by the World Monument Funds, Téréba Togola codirected archaeological excavations at Jenné-jeno from December 1996 to February 1997.

After Téréba Togola became the Director of National Arts and Culture (DNAC) his tasks included the preservation and promotion of cultural heritage. Under his leadership, the DNAC was restructured. This led in 2001 to the creation of two different entities: the National Directorate of Cultural Heritage (DNPC), which manages the inventory, protection, restoration, and the

dissemination of national cultural heritage, and the National Directorate for Cultural Action (CAA), which works to promote the creation of artistic works and their dissemination.

Dr. Togola became the head of the DNPC, where under his direction some outstanding actions were undertaken, including the design and realization of the Cultural Map of Mali (2004), the inscription in 2004 of the Tomb of Askia on the World Heritage List, the withdrawal of the ancient city of Timbuktu from the List of World Heritage in Danger (2005), and the listing of the Jaaral and Degal cultural space (i.e., the crossing of the river *Diaka* in Diafarabé and the descent of cattle in the *bourgoutières* in Dialloubé-Téninkoun) in 2005 as a masterpiece of oral and intangible world heritage. Dr. Togola largely contributed to the restoration of the Komoguel mosque in Mopti, classified as national heritage in 2005, and of the historic city of Hamdallaye, classified as national heritage in 2007. In addition, he contributed to fundraising for the restoration of Fort Medina (Kayes), which was classified as a national heritage site in 1992. Téréba Togola also continued archaeological research, such as on the site of the Kankou Moussa mosque, where an ongoing research program was initiated in 2003–2004 in collaboration with the Swedish International Development Agency (SIDA-SAREC) and the National Museum of Ethnology, Osaka (Japan).

Tomatoes: Origins and Development

Tim Denham
Archaeological Science Programs, School of Archaeology and Anthropology, ANU College of Arts and Social Sciences, The Australian National University, Canberra, ACT, Australia

Basic Species Information

Although Linnaeus (1753) classified tomato as *Solanum lycopersicum*, the taxonomy of tomato has been subject to great debate. Various

alternative taxonomic classifications have been proposed, principally as *Lycopersicon esculentum*, which is still in common usage (e.g., Doebley et al. 2006). Multiple genetic studies now unequivocally confirm the tomato as belonging to the genus *Solanum*. Confusingly, some researchers split tomatoes into the weedy *S. lycopersicum* var. *cerasiforme* and the cultivated *S. lycopersicum var. lycopersicum*, whereas others refer solely to *Solanum lycopersicum*. The latter classification is followed here.

Tomatoes are one of the most significant, in terms of production, crop plants in the world. Although generally considered to be a fruit, the tomato is also classified as a vegetable. Tomatoes are rich sources of several nutrients and vitamins. Tomatoes are herbaceous perennials, although in many growing environments they behave as annuals; for example, they tend to die off after frost or dry periods (Peralta and Spooner 2007). Tomatoes exhibit a wide climatic tolerance, although cultivated varieties require regular watering. They are diploids, are grown from seed, and exhibit considerable morphological variability. Tomatoes are considered a model plant to study the genetics of diploid plants (Peralta and Spooner 2007) and for studying fruit development (The Tomato Genome Consortium 2012).

Wild tomatoes are native to western South America, extending in altitude from near the coast to the high Andes (above 3,000 m altitude) and extending from central Ecuador, across Peru, to northern Chile. The climatic and environmental diversity of environments has contributed to the diversity of wild tomatoes.

Major Domestication Traits

Different theories have been proposed for the region of tomato domestication (following Peralta and Spooner 2007: 14–17). Since De Candolle (1884), a Peruvian hypothesis has predominated based on a combination of botanical, historical, and linguistic inferences. However, Jenkins (1948) proposed an alternative Mexican hypothesis based on multidisciplinary evidence, primarily the center of cultivar diversity (using morphological criteria), as well as more anecdotal historical sources and linguistic inferences. Questions regarding the origin and domestication history of tomato have only recently been clarified by genetic analyses.

Although there are several hundred varieties of cultivated tomato, they exhibit extremely limited genetic variability from each other and from the closest wild ancestor. For example, genomic sequences of an inbred (domesticated) tomato cultivar 'Heinz 1706' and the closest wild relative, *Solanum pimpinellifolium*, exhibit limited genetic divergence and recent admixture (The Tomato Genome Consortium 2012). Despite limited genetic variation, there is considerable morphological variation among cultivated varieties and between cultivars and wild types.

Hybridization between wild and cultivated species of tomato has been documented for *Solanum pimpinellifolium* and *Solanum lycopersicum*. As Peralta and Spooner (2007: 13) observe: "The reciprocal introgression of traits into both taxa generates complex morphological [and presumably genetic] gradation between them that makes their taxonomic identification difficult." Against this backdrop of complexity, specific genetic attributes of cultivated tomatoes have been identified that control for domestication traits, primarily fruit size (*fw2.2*, the "domestication gene" in tomatoes; Zeder et al. 2006), as well as differences between cultivated varieties, such as synchronicity and timing of fruit ripening and fruit shape (Doebley et al. 2006). Although these genetic attributes may be present in wild plants, they are more frequent in cultivated varieties of tomato (Nesbitt and Tanksley 2002). Significantly, recent genetic improvement of tomato has been designed for increased shelf life and synchronous fruiting, which has seemingly occurred at the expense of flavor (ACTI 1989).

Despite limited genetic variation, there is phylogenetic structure that enables aspects of the geodomestication process to be inferred:

> . . . we hypothesize that, based on the molecular and morphological data presented, *S. l. cerasiforme* originated from *S. pimpinellifolium*. The tomato was later domesticated [to *S. l. lycopersicum*] from *S. l. cerasiforme* in a process composed of several

phases: first, a predomestication was carried out in the Andean region, during which *S. l. cerasiforme* developed a notable morphological diversity that included bigger fruits, which are even today being cultivated as small-fruited tomatoes. Those materials were then carried to Mesoamerica and it was there that the true domestication occurred, thus creating the traditional big-fruited tomato varieties. From there, the Spaniards took tomatoes to Spain and Italy, and from there they spread to the rest of the world (Blanca et al. 2012: e48198).

Although the terminology of predomestication and "true domestication" may not be helpful and may best be characterized as stages of domestication, Blanca et al. (2012) clearly identify a domestication cline from the most closely related wild tomato species (*S. pimpinellifolium*) to the weedy *S. lycopersicum* var. *cerasiforme*, to the cultivated *S. lycopersicum var. lycopersicum*. Additionally, the staged interpretation of tomato domestication encompasses aspects of both De Candolle's Peruvian and Jenkins' Mexican hypotheses.

Timing and Tracking Domestication

Unfortunately, there is extremely sparse archaeological data for tomatoes to clarify genetically based or earlier scenarios of domestication. No pertinent data predate approximately 1,000 years ago. There are also uncertain claims for depictions of tomatoes on ceramic spindle whorls dating to 500–1000 CE in Columbia (McMeekin 1992), but these may represent other flowering *Solanum* species, including potatoes (Peralta and Spooner 2007: 16–17). Sufficient taxonomic specificity in archaeobotanical and stylistic interpretations is also lacking to assess the relevance, if any, of these finds for understanding tomato domestication.

Historical sources show that tomatoes were grown in Mexico at the time of Spanish conquest. Tomatoes were subsequently introduced to Europe in the early to mid-sixteenth century, in the decades immediately following that conquest. Initially, plants were grown as curios, medicinal plants or ornamentals because they were considered inedible or poisonous (Peralta and Spooner 2007: 17–19). Tomatoes were first grown for food during the seventeenth and eighteenth centuries in southern Europe, especially in Italy.

Although De Candolle (1884) speculated that tomatoes may not have been domesticated long before European colonization of the Americas, in the absence of robust archaeological evidence, this is an open question. At present, the geodomestication pathways of tomato domestication can be tracked using genetics and other botanical attributes. The historical time depth for these processes is unclear. Although historical linguistics can offer valuable insights (e.g., Campbell and Kaufman 1976), the history of tomato domestication awaits an archaeobotanically derived chronology.

Tombs, Etruscan

Stephan Steingräber
Dipartimento di Studi Storico-Artistici, Archeologici e per la Conservazione, Università di Roma Tre, Rome, Italy

Introduction

Etruscan tombs, Etruscan necropoleis/cemeteries, and Etruscan tomb architecture belong to the most interesting, exciting, and expressive groups of monuments of Etruscan civilization. They furnish a great deal of precious information about Etruscan culture, art, architecture, life, burial customs, funeral rites, and religion. They often reflect historical, economic, and social changes as well. Undoubtedly, the Etruscans invested many financial resources and architectural, technical, and artistic skill in their necropoleis and tombs. Thanks to the discoveries and excavations of thousands of tombs since the Renaissance period, we know much more about the world of the dead than the world of the living in Etruria.

The first discoveries of important Etruscan tombs and tomb monuments date to the Renaissance (late fifteenth–early sixteenth century CE), especially in Tuscany and in the area of Viterbo. It is possible that even great Renaissance artists such as Leonardo da Vinci and Michelangelo drew inspiration from some Etruscan tomb or tomb monument. The second half of the eighteenth century CE (the period of the so-called Etruscheria) and the nineteenth century CE (the period of Romanticism and Neoclassicism) were particularly rich in terms of discoveries (Dennis 1848). Even today, new tombs are discovered both by regular and clandestine excavations, although the main scholarly interest in recent decades lies more in the archaeology of Etruscan settlements and sanctuaries.

Among the most recent and important discoveries we can mention the Cutu Tomb at Perugia, the new excavations around the Tomb of the Five Chairs at Cerveteri (Fig. 1), the Tumulo del Sodo II at Cortona-Camucia, the two Doganaccia Tumuli at Tarquinia (Fig. 2), the Tomb of the Demons at Cerveteri-Greppe Sant'Angelo, the painted Tombs of the Blue Demons at Tarquinia, of the Infernal Quadriga at Sarteano near Chiusi, and of the Roaring Lions at Veii, as well as the restoration of the Cuccumella Tumulus at Vulci and the "Little Petra" (rock tombs) in a former quarry at Populonia. There are only a few general, overview publications on Etruscan necropoleis and tombs which we owe mainly to archaeologists such as F. Prayon and J. P. Oleson (Akerström 1934; Demus-Quatember 1958; Prayon 1975; Oleson 1982; Colonna 1986; Prayon 1986; Prayon 2000; Steingräber 2010).

Definition

We have to deal with an enormous amount of monuments and materials dating from the ninth to the first century BCE in all areas of Etruria including even the "colonial" areas in northern Italy (Emilia-Romagna) and Campania in the south. We can distinguish between single tombs, small groups of tombs, and true necropoleis. Some of the Etruscan necropoleis such as the Banditaccia of Cerveteri belong among the most extensive of the ancient Mediterranean world (Drago Troccoli 2006). Concerning typology, we

Tombs, Etruscan, Fig. 1 Cerveteri, Banditaccia necropolis: Tomba delle Cinque Sedie = Tomb of the Five Chairs (seventh century BCE)

Tombs, Etruscan, Fig. 2 Tarquinia, Monterozzi necropolis: chamber tomb partly reconstructed in the Doganaccia Tumulus (seventh century BCE)

must distinguish strictly between "tombs" on the one hand and "tomb/burial monuments" on the other hand. The most important aspects regard typology, chronology, topographical diffusion/extension, context in the necropolis, architectural elements, decoration elements, elements for the ancestor cult, and burial gifts. It also must be noted that for Etruria, tomb architecture is a partial and precious source of proxy evidence for the largely destroyed and lost Etruscan domestic architecture (Prayon 1975). There are of course different approaches to this extremely extensive and complex topic – a more technical-architectural one, a more art-historical one, a more religious one, and a more social-economic one.

Historical Background

Etruscan tombs cover a long period from the early Iron Age (so-called Villanovan period) to the late Hellenistic period, which means from the ninth and eighth to the second and first centuries BCE. Often they clearly reflect political, economic, social, and religious changes of Etruscan civilization (Izzet 2007; Riva 2010). Thus, the most robust periods of Etruscan civilization such as the Orientalizing and Archaic phases (seventh–sixth century BCE) and the late Classical and early Hellenistic phases (fourth–third century BCE) offer us particularly monumental and rich examples of tomb architecture and burial gifts both in North and South Etruria. Concerning Etruscan tomb architecture, we must distinguish strictly between the different territories of Etruria characterized by different geological, cultural, and social-economic situations.

Key Issues/Current Debates

The key issues of current research are:

Necropoleis: Planning, Organization, Extension, and Development

In the Villanovan period (ninth–eighth century BCE), the necropoleis were still isolated from each other, but during the Orientalizing and Archaic periods, they extended until they entirely surrounded the inhabited area and even outstripped it in area. The different geological and geographical conditions in South and North Etruria resulted often in different forms of cemeteries and tombs. In Cerveteri, the Banditaccia necropolis – the most impressive and best preserved necropolis of Etruria – and in Orvieto, the Crocifisso del Tufo necropolis are outstanding and extremely instructive examples, reflecting in part the layout of the cities themselves. During the sixth century with the rise of a new middle class, hundreds of small tumuli (tumuletti), and later cube tombs, were planned and erected according to the direction of the necropolis' streets and accessible directly from them. After the middle of the sixth century, parts of the cemeteries are characterized by a kind of Hippodamian system with an orthogonal network of roads and rectangular squares and mostly uniform cube tombs which is not only a sign of a more intensive use of space but also a clear reflection of new tendencies in urban system (such as in Marzabotto near Bologna after 500 BCE) (Steingräber 2003). At the same time, the necropoleis reflect social changes and probably new laws and norms intended to limit conspicuous consumption as part of the funeral ritual.

Tombs: Typology, Chronology, Diffusion, Architectural Elements, and Decorations

The Etruscan word for tomb is "*suthi*." Among the main tomb types, we have to mention pozzo/pozzetto tombs (well/pit tombs) for cremation burials, fossa tombs, loculus tombs, niche tombs, chamber tombs, cassone tombs (Vulci), sarcophagus, and stone cist tombs. According to the different regions, sites, geological conditions, local traditions, and social status, there is a greatly varied typology (Steingräber 1981). A very important change in burial custom took place in the early seventh century with the transformation of larger fossa tombs into chamber tombs destined for the burial of family groups. We can observe this change from single to collective burial particularly well in the extended cemeteries of Cerveteri. The general tendency of monumentalization is well documented in South Etruria not only in Cerveteri and its territory (Blera, San Giuliano, San Giovenale) but also in Vulci, Tarquinia, and Veii, too. In North Etruria, the chamber tombs and the tumuli are mostly built in limestone or sandstone blocks and slabs (Populonia (Fig. 3), Vetulonia, Artimino, Quinto Fiorentino, Castellina in Chianti, Cortona), whereas in South Etruria, hollowed-out structures in the soft volcanic tufa stone prevail (Fig. 4). Characteristic for North Etruria (especially between Volterra and Florence) in the later Orientalizing period (second half of seventh and early sixth century) are round burial chambers with a false cupola and sometimes a central pillar (the so-called tholos tombs). While these are reminiscent of Bronze Age Mycenaean tholoi from the Aegean world, they in fact reveal special

Tombs, Etruscan, Fig. 3 Populonia, San Cerbone necropolis: Tomba dei Letti funebri = Tomb of the Funeral Beds with stone beds (seventh century BCE)

Tombs, Etruscan, Fig. 4 San Giuliano, Valle Cappellana: chamber tomb of Valle Cappellana I with two columns (around 600 BCE)

architectural connections with the Sardinian nuraghe. An earlier predecessor, we find only in Populonia toward the end of the ninth and the beginning of the eighth century in a much smaller size but already characterized by a circle of slabs and a small tumulus, a single entrance, a circular chamber, and a false cupola. During the Orientalizing period in Vetulonia and Populonia, the circular false cupola rests atop a square chamber. The tombs of Cortona, Castellina in Chianti, and Artimino are characterized mainly by the arrangement of rectangular chambers with corbelled vaults along a longitudinal axis. The development of tomb architecture during the seventh and sixth centuries BCE in South Etruria – particularly at Cerveteri – is extremely varied and instructive.

Prayon (1975) divided these tombs into six main types (A–F) according to their ground plans, type of entrance corridor (dromos), door, and window shapes; types of roofs, ceilings, and "furniture" such as tomb beds, sarcophagus beds, benches, thrones, chairs, baskets and altars, columns, pillars, capitals, and profile bases, and type of monument and exterior architecture. Those tombs often reproduce many details of the interiors of Etruscan houses (Drago Troccoli 2006). The Regolini-Galassi Tomb and the Tomb of the Hut or Thached Roof belong to the oldest chamber tombs in Cerveteri with a long open dromos and the chambers situated on the longitudinal axis. Whereas the corbelled vault of the Regolini-Galassi Tomb is built in tufa slabs, the two chambers of the other tomb are completely hollowed out and – concerning the vaults – clearly influenced by contemporaneous hut architecture. A very characteristic tomb type (Prayon type D) was common in Cerveteri and its territory during the late seventh and the first half of the sixth century and is clearly influenced by house and palace architecture (as in Veii and Acquarossa). It is characterized by a large antechamber and three burial chambers behind it, often with a rich "furnishing" (as in the Tomb of the Shields and Chairs in Cerveteri). The same ground plan is documented after the middle of the sixth century in temple architecture, too (the so-called templum tuscanicum of Vitruvius, *Arch*. 4.7). A major change occurs toward the end of the sixth century when the tombs – especially in the Cerveteri area – no longer imitated actual houses and consisted normally only of one square chamber with simple benches along the walls. This quite simple and monotonous one room type remained typical for the following centuries. Only after the middle of the fourth century BCE some tombs of new aristocratic families – especially in Cerveteri, Tarquinia, and Vulci – become again more richly decorated with architectural elements (pilasters, loculi/wall niches, beds) and painted or stuccoed elements (as in the famous Tomb of the Reliefs in Cerveteri belonging to the Matuna family). These imitated in an abstract way the central part of contemporary dwellings (atrium houses), while the smaller rooms reflected the bed chambers (*cubicula*) of those houses; in the tombs, these are reduced to simple loculi used for burials. The burial of the tomb's founding couple was particularly emphasized normally by a huge alcove in the center of the back wall according to the idea of heroization of the deceased (as in the Tombs of the Reliefs, Alcova, and Torlonia in Cerveteri and in the Mercareccia Tomb in Tarquinia). The huge number of burials of several generations underlines the continuity of the gentilician groups. Quite different is the tomb type with the barrel vaulting built in stone blocks which is documented first in the early Hellenistic period in Cerveteri (Tomb of the Demons in Località Greppe Sant'Angelo) and Orvieto and in the middle Hellenistic period mainly in the territories of Chiusi, Cortona, and Perugia. Completely different is the Velimna/Volumni Tomb at Perugia (second century BCE), with its symmetrical layout of several chambers grouped around a T-shaped nucleus resembling the patrician *atrium-tablinum* house type, which was obviously of Etrusco-Italic origin and goes back to the Archaic period.

Tomb Monuments: Typology, Chronology, Diffusion, and Elements of Decoration

The Etruscan word for a tomb monument, cippus, or sema is "*cana*" (Steingräber 2010). Among the tomb monuments, we have to distinguish between stone circles (interrupted and continuous, especially in Vetulonia and Marsiliana d'Albegna); tumuli and tumuletti (especially in the seventh and first half of the sixth century); cubes, half cubes, and false cubes (from the second half of the sixth century to the third century); houses (mainly in the sixth century); porticus (mainly in the sixth and third centuries); and temples, aediculae, and tholoi (mainly in the third century). A great change was connected with the construction of large tumuli (diameters up to 80 m) both in South and North Etruria (Fig. 5) replacing the small "Archaic tumuli" and with the definitive confirmation of a new leading aristocratic class, the so-called principes. The large tumuli of the Orientalizing period – characterized normally by a base with a profile – often contain more chamber tombs, in a few cases as many as six or seven.

Tombs, Etruscan, Fig. 5 Cerveteri, Banditaccia necropolis: tumulus with chamber tomb (seventh century BCE)

Tombs, Etruscan, Fig. 6 Populonia, San Cerbone necropolis: Aedicula tomb (sixth century BCE)

These tombs go back often to different periods and present a different typology. Each tumulus belonged to a particular family or *gens* and served for several generations. The oldest tomb in a tumulus is always oriented toward the northwest, which means toward the section of the underworld gods on the Etruscan celestial partition. After the middle of the sixth century BCE, the cube tombs with their square appearance prevailed particularly in Cerveteri, in the South Etruscan rock tomb area (Blera, San Giuliano, Tuscania), and in Orvieto. In Populonia, the tumuli were replaced by built aedicula tombs with characteristic gabled roofs (Fig. 6) and smaller sarcophagus and stone cist tombs. Tomb monuments of the second half of the fourth and the third century became richer

again as their external facades were often revaluated by architectural and sculptural decorations. In some cases, the old fashioned tumulus was used again as a tomb monument (Tomba Torlonia at Cerveteri).

Elements for the Cult of the Dead: Typology, Functions, and Materials for the Rites and Sacrifices

Etruscan tombs and tomb monuments did not serve only as burial places but also as sites for funeral rites and for the worship of the dead. Particular – mostly architectural – elements were destined exclusively for the cult and rites in honor of the deceased and ancestors (Steingräber 1997). Some of these elements are of monumental character and size. In Cerveteri (Tomb of the Five Chairs) (Fig. 1), Vulci, and San Giuliano (Cima Tomb), we find tomb chambers with remains of altars, thrones and chairs, tables, and chests in stone, but without any burials which functioned exclusively as cult rooms for sacrifices and burial rites. Many tumuli – specially in Cerveteri – have ramps or added platforms (like in Artimino) or terraces. Most cube tombs have lateral stairs which allow one to climb to the top of the monument, obviously for ritual purposes. The upper platforms of the cube tombs have the size and function of monumental altars. Some special areas with benches could be used for funeral banquets. The most impressive example is the so-called terrace altar of the Tumulo del Sodo II in Cortona-Camucia decorated with palmettes of Ionic style and two sculptural groups dating from the late Orientalizing period. From this monumental terrace altar, one could climb up to a naiskos/aedicula on the top of the huge tumulus. Both structures were clearly intended for funeral rites and ceremonies. Open squares and "ritual theaters" are documented also in Grotta Porcina near Blera (in combination with a round altar), Vulci (in front of the Cuccumella tomb), and Tarquinia (in front of the Luzi tomb).

Rock Tomb Architecture: Diffusion, Typology, Chronology, and "Ideology"

This phenomenon is unique in Italy and characteristic of the inner parts of South Etruria (today mainly the Province of Viterbo) from the first half of the sixth to the third/second century BCE (Colonna di Paolo 1978; Steingräber 2009). We find the most important examples of rock tombs – with a rich typology including cube, house, aedicula, temple, porticus, and tholos tombs – in the Archaic period in Tuscania (Fig. 7), San Giuliano, and Blera and in the Hellenistic period in Norchia, Castel d'Asso, and Sovana (Figs. 8, 9, and 10). The most common type was the cube or

Tombs, Etruscan, Fig. 7 Tuscania, Pian di Mola: rock tomb in house shape with porticus (sixth century BCE)

Tombs, Etruscan, Fig. 8 Sovana: model of the Ildebranda Tomb = rock temple tomb (third century BCE)

Tombs, Etruscan, Fig. 9 Sovana: pediment of the Tomba dei Demoni alati = Tomb of the Winged Demons (third century BCE)

half cube tomb most probably inspired by the – partly constructed – cube tombs of Cerveteri. Influences of palace architecture manifest themselves particularly in the facade of the house tomb with porticus at Pian di Mola near Tuscania of the early Archaic period (Fig. 7). The most noble rock tombs such as the temple and porticus tombs of Norchia (Doric tombs, Lattanzi Tomb) and Sovana (Ildebranda (Fig. 8) and Pola Tomb) reveal influences from temple and palace architecture. Great attention and care were paid especially to the external appearance of the rock monuments and facades characterized by profiles, doors, and false doors of the so-called Doric type and by painted and sculpted decorations (Figs. 9 and 10). Most of them not only served as burials but also as cult places and monumental altars.

Tombs, Etruscan, Fig. 10 Sovana: Tomba della Sirena = Tomb of the Siren, an aedicula tomb with a Skylla relief in the pediment and a sculpture of a demon (third century BCE)

Tombs, Etruscan, Fig. 11 Bomarzo: "Piramide" = "Pyramid," a monumental rock altar (first century BCE–first century CE)

Rock Monuments of the Late Etruscan and Roman Period

The Etruscan tradition of rock monuments mostly of funerary character continues even in Roman times, specially in the first century BCE and the first century CE and particularly in the area between the Monti Cimini and the Tiber valley around Bomarzo (Fig. 11), Soriano nel Cimino, and Vitorchiano. They offer a rich typology and are partly characterized by Latin inscriptions indicating the names – often of Etruscan origin – of the deceased, the patrons, and some divinities such as the Bona Dea (Steingräber and Prayon 2011).

Tombs, Etruscan, Fig. 12 Cerveteri, Banditaccia necropolis: monumental stone cippus in house shape near the Tomba delle Cinque Sedie = Tomb of the Five Chairs (seventh century BCE)

Burial Gifts: Composition, Materials, Quantity/Amount, Quality/Value, Provenance, Local and Foreign Elements, and "Ideology"

The composition, materials, quantity, and quality of the burial gifts – in most cases unfortunately, not more complete and intact – give us a lot of information about age, sex, social status, and taste of the deceased and of course about chronology and duration of the use of a tomb. In addition, the composition of the burial gifts including often both local and foreign objects informs us about the economic and cultural relations between the respective Etruscan town and other Etruscan towns and foreign areas. Especially in the Orientalizing period, the burial gifts of the aristocratic tombs (*principes*), such as Regolini-Galassi Tomb in Cerveteri, were particularly rich including numerous imported exotic objects from different areas in the Near East, Egypt, and different areas of the Greek world.

Varia

Other important aspects concern tomb inscriptions, cippi, tomb sculptures, and tomb paintings. Tomb inscriptions are quite rare in the early periods apart from the Orvieto tombs (sixth century) but later documented on cippi and facades such as in Norchia and Castel d'Asso and in the painted tombs (mainly in Tarquinia). In the case of Orvieto's Crocifisso del Tufo necropolis, the inscriptions give us information about the different provenance of the tomb owners (from Umbria and even from the Celtic area). Stone cippi could be erected in front of the tomb entrance, upon the tomb monument, or sometimes even in the tomb and indicate specific burials (Fig. 12). Their size, material, and typology differ according to local customs and different periods in Etruria. Sculptures of wild animals and monsters as "guardians" in front of the tomb monument or tomb entrance – particularly in Vulci – were probably of an apotropaic character and especially common in the Archaic period. The phenomenon of tomb painting is typically Etruscan but was mainly concentrated in Tarquinia. Painted chamber tombs are documented in Etruria from the early seventh century until the late third century BCE. In addition to those painted tombs at Tarquinia, examples are also known from Veii, Cerveteri, Vulci, Orvieto, Chiusi, and some smaller sites. The rich and colorful iconography of these tomb paintings furnishes us with a great deal of information about Etruscan life and afterlife (Naso 1996; Steingräber 2006).

International Perspectives

Concerning the international/Mediterranean context of Etruscan tomb architecture and burial gifts, the following aspects are of particular interest:

1. Foreign influences, models, and parallels from/in Asia Minor (particularly in Phrygia, Lydia, Lycia, and Caria), Cyprus (Salamis), Syria (Ugarit), Macedonia, Apulia, Campania, Umbria, Sabina, and *Latium vetus*.
2. The spread of the so-called Macedonian barrel-vaulted tomb type via North Apulia/Daunia and Campania to South Etruria (Cerveteri, Orvieto) and later to North Etruria (Chiusi, Cortona, and Perugia).
3. Hellenistic temple and porticus tombs in the South Etruscan rock tomb area (Norchia, Sovana) clearly influenced partly by the mausolea and heroa of Asia Minor (concerning the general conception and "ideology") connected with the idea of heroization of the deceased and partly by decoration elements from Magna Graecia and Apulia.
4. The burial gifts in Etruscan tombs – especially those of the seventh and sixth centuries BCE – offer us a lot of information about the international connections between Etruria and the Near Eastern areas (Cyprus, Phoenicia, North Syria, Assyria, Urartu, Egypt), the Greek world (Attica, Corinth, Euboea, Aegean islands, Eastern Greece/Ionia, Magna Graecia, and Sicily), Asia Minor, Carthage, and Sardinia.

Future Directions

Some of the main Etruscan necropoleis such as the Banditaccia necropolis of Cerveteri are not yet completely and sufficiently published. We should make every possible effort to close these painful gaps. Main desiderata should be considered by the way more international cooperation, the creation of valid and helpful databases, and still more paleoanthropological, paleozoological, and paleobotanical research for the reconstruction of general living conditions in Etruria and the preparation and publication of a well-organized handbook/manual on Etruscan necropoleis, tombs, and tomb architecture including the most recent excavations, discoveries, and research.

Tombs, Greek (Iron Age)

Fabio Colivicchi
Department of Classics, Queen's University, Kingston, ON, Canada

Introduction

Funerary evidence is one of the traditional fields of Greek archaeology, but only in relatively recent times has it developed as a major source in its own right for the study of Greek culture and society, the focus being traditionally on great public architecture and figurative art.

Historical Background

Among the many changes that took place in Greece between the end of the Bronze Age and the beginning of the Iron Age are those in burial

customs. Multiple burials disappear and individual pit or cist tombs become the new standard. Cremation also establishes itself, even though not across the whole Greek world and not all at the same time. In important regions such as Argolis, Boeotia, and some of the islands (Sporades, northern Cyclades, Kos), inhumation was still in use until the end of the eighth century BCE. In the Peloponnesus, cremation remains a minority practice. On Crete cremation is prevalent, but there the traditional collective graves remained in use. In many regions, the two practices coexist, with a ratio variable from one site to another. The adoption of one rather than the other ritual also depends on sex and age, as illustrated by an exceptional burial of the tenth century BCE, the so-called *heroon* of Lefkandi, a monumental apsidal building with two deep trenches, one for horse burials and the other for a cremated man and a inhumated woman. In general, cremation was reserved for adults, while children were inhumed and infants buried in large pots (*enchytrismos*).

Athens is the best known case study for the development of Iron Age burial customs (Morris 1987). Starting from the Protogeometric period (1050–900 BCE), cremation is standard for adults, or at least the vast majority of them, while children are inhumed. It appears that some burial grounds are used predominantly for adults and others for children. Indicators of sex are objects – weapons and ornaments – and the shape of the ash container, neck-handled amphorae for men and shoulder-handled or belly-handled for women. The cinerary urn is buried in a trench along with pyre debris and burnt offerings. Grave goods are usually few, chiefly pottery vases, pins, fibulae, rings, and bracelets. In the Early Geometric (900–850 BCE) graves, markers appear, undecorated stones and/or large vases, amphorae or craters, the latter reserved for men. Over the ninth century BCE and especially in its second half appear elite tombs with rich sets of grave goods including weapons, metal objects, gold jewelry, and ivory and faience imports, (Fig. 1) while child tombs become rare and the overall number of graves decreases. In the eighth century BCE, inhumation returns as the main ritual, but cremation is also found, in some cases in burials with bronze cauldrons as ash containers. These may allude not only to banquets and consumption of boiled meat, but also to myths in which cauldrons are used for magic rituals of regeneration and rebirth. Vases used as grave markers grow to monumental size and are decorated with scenes of funerary ritual such as the laying out of the body, and its being borne out to the grave. The second half of the eighth century BCE brings about many changes. Large family burial grounds featuring many tombs of children appear, and there is high variability in the composition of sets of grave goods and in the details of funerary behavior. In the last decade of the century, elite tombs are found mostly in the rural districts, while burials become more standardized in the city cemeteries. These new developments have been interpreted against the background of the formation of the polis and its ideology.

Tombs, Greek (Iron Age), Fig. 1 Athens, male cremation burial, c. 900 BCE. (From *Hesperia* 21, 1952)

A very different trend is visible in the seventh century BCE, not only in the number of graves, but also in the burial customs. Cremation returns and there is a strong increase of practices that give the dead a heroic status (e.g., Houby-Nielsen

1996). The body is burnt directly inside the trench (a ritual that in the *Iliad* is reserved to Patroclus), together with very few or no objects, while other offerings are found in deposits separated from the grave, among which the so-called offering ditches. These are remains of table-like structures made of wood and bricks on which food and fine banquet pottery was burnt. After the fire had died down, the ditches were sealed and covered by mounds or funerary buildings topped by large vases or stone markers. Mounds of the seventh century are clustered in family plots and remain in use sometimes for a very long time.

In the sixth century BCE, some aspects of the funerary ritual become simpler (end of the offering ditches, smaller mounds), perhaps as the result of laws against luxury in funerals mentioned by Cicero (*de Leg*. 2.64). However, stone stelai and statues are now largely used as a permanent sign of elite status, which ensure the lasting memory of the name and the rank of the dead. Two new large mounds are also built, one according to some scholars for the *genos* of the Alcmeonids, the other for foreign ambassadors of the period of the tyrants. The archaic cemetery near the agora, used between c. 560 and 500 BCE, has been attributed to the Peisistratids because of its location. However, it seems unlikely that these tombs, which were protected by a wall that was repaired after the Persian invasion and were respected for centuries, actually belonged to the tyrants. More likely this is a burial ground relative to the Areopagus that ceased to be used when the city space was more rigorously defined.

Outside of Athens evidence is less abundant, but some trends are visible. In the eighth century BCE at Argos, where inhumation was the norm, the upper classes used large cist tombs, among which some had full panoplies of weapons, probably alluding to the ideal of the Homeric hero, while ordinary burials are in large jars. In the same period, exceptional offerings, including monumental bronze tripods, were dedicated in the city sanctuaries as a clear demonstration of the emergence of an aristocratic class that publicly displays its status. At the end of the eighth century BCE, weapons are not included in burials anymore, a trend that is also found in the rest of the Greek world. With the disappearance of the tombs of hero warriors, exceptional offerings are exclusively reserved for the sanctuary, the common space where the aristocracy can display its status in a less strictly personal and familiar setting. The formation of an egalitarian ideology within the ruling class may also be reflected in the standardized Argive burial practices of the seventh century BCE, based on multiple burials inside large jars.

The model of the Homeric hero warrior is also important in Euboea. At Lefkandi, tombs cluster around the tumulus built on the Protogeometric *heroon*. At Eretria, adults are cremated either directly in pits or on pyres and their remains are collected in bronze cauldrons. A small group of seven adult graves arranged around a central male burial is exceptional not only because of the use of bronze cauldrons for men and women alike and their select grave goods – weapons and ornaments only – but also because of their location and their later history. When the city wall was built in about 680 BCE, the small cemetery, now just inside the West gate, was transformed into a hero shrine protected by an enclosure and marked by a triangular monument. This transformation is considered by some a strategy of the polis to appropriate the ancient "heroes" turning them into public figures, while others think that it was actually their own *genos* who, by making the tombs of their ancestors the object of public cult, claimed for the family a permanently prominent role in the developing polis.

Aspects of this funerary tradition are passed to the Euboean western colonies in Italy. At Pithecusa, there are no "hero" graves, but the burial customs are similar, with cremation for adults, inhumation in pits for adolescents, and *enchytrismos* for infants. The cemetery is organized in tight family clusters. At Cuma, however, are also present elite cremation burials with bronze cauldron. Tomb 103 of Fondo Artiaco stands out for its rich set of personal ornaments and silver vases, which compares with princely burials of contemporary Etruria, Latium, and Campania. Between the late eighth and the early seventh century BCE, Euboean funerary customs influenced those of the elites of central Tyrrhenian Italy and constituted one of the components of a

common culture which crossed ethnic difference and emphasized common class belonging.

The development of strong aristocracies in the Archaic age may also account for the reappearance of chamber tombs in some regions of the Greek world such as Cyrene, Thera, Aegina, Samos, Miletus, and Rhodes. Crete is a special case because of its traditionalism, which is the reason for the continuing use or reuse of *tholos* tombs and the fortune of chamber tombs. In some Eastern Greek poleis (Chios, Clazomenae, Ephesus, Smyrna, Larissa-on-the-Hermos, Pitane), elite tombs, frequently in sarcophagi, are covered by tumuli, perhaps after the Lydian model. Chamber tombs, some of which imitate banquet halls (Fig. 2), are also found at Taras until c. 470 BCE, when these and other manifestations of aristocratic culture fall into disuse, probably because of local political developments (Lippolis 1994). More isolated occurrences are found in other areas, such as the monument of Menekrates on Corfu, a massive cylindrical building of a type which is also known at Athens.

In the fifth century, there is a general decrease of funerary luxury while the city structures develop and increase their control. In Athens, funerary sculpture declines sharply and monumental tombs cease, the exception being the continuing use of ancient mounds, probably a surviving privilege of aristocratic *genoi*. In the cemeteries of Athens, inhumation is the prevailing ritual, but cremation does not disappear and is found in variable ratios in different burial grounds. Adults are buried in individual pit tombs, pits lined with slabs, tile graves, and sarcophagi, while children are buried in reused

Tombs, Greek (Iron Age), Fig. 2 Taras, chamber tomb. (From Lippolis 1994)

amphorae, pots, clay tubs, small tile graves, and small sarcophagi. Cremation is both primary and secondary, with a variety of ash containers including bronze vases. The overall impression of homogeneity is in part contradicted by the differences between cemeteries both in ritual and selection of grave goods, for instance, in the presence or absence of *lekythoi* (bottles for perfumed oil), on which tombs and grave markers are frequently represented (Fig. 3). In general, burials are accompanied by only a few objects, including vases for perfumed oil, cups, bowls, and jugs, and small lidded containers.

In the last quarter of the fifth century BCE, when the polis structures are under pressure because of the Peloponnesian War, leveling ideology seems to be less effective. Funerary luxury reappears in form of figured stelai, monumental tombs and family enclosures lined along the roads entering the city. Selection of individuals with formal burial is now stricter and the number of tombs of children drops.

Tombs, Greek (Iron Age), Fig. 3 Athenian white-ground lekythos with woman at a tomb. (From *Annali dell'Istituto Orientale di Napoli, sezione di Archeologia e Storia Antica* 1988)

In the fifth century BCE, similar trends of standardization of burial practices are also found in the rest of Greece. One of the most spectacular cases is the South cemetery of Poseidonia (Italy), established in the early fifth century BCE following an extremely regular layout (Cipriani 1989) (Fig. 4). Graves uniform in type and size (pits and cists) and arranged in parallel rows occupy intensively all space available. There is no distinction between family plots, which are however visible in the North cemeteries, established when the city was founded c. 600 BCE. When present, objects in tombs are few and mark sex and age of the dead, and its related social role. Strigils and oil flasks alluding to the gymnasium are reserved for young men. This image of an ordered and egalitarian community, where differences depend on age and sex, not on birth and status, is projected at the time when the urban area undergoes significant transformations emphasizing collective identity, such as the construction of a hero shrine of the founder in the late sixth century BCE and of a round assembly building in the early fifth century BCE.

The most striking exceptions to the general rule are mostly limited to peripheral areas at the margins of the polis world, such as Sindos on the Thermaic Gulf, where burials are exceptionally rich. Tombs feature bronze objects, gold jewelry, weapons, miniature models of banquet instruments and wagons (four-wheeled for women and two-wheeled for men), and gold-leaf masks covering the face of the deceased. The burials of Sindos still represent the traditional image of the aristocratic *oikos* based on war, banquet, and luxurious lifestyle, which had disappeared in the rest of Greece with the full development of city structures.

However, as mentioned for Athens, in the last decades of the fifth century BCE, signs of the crisis of the egalitarian model of classical polis are visible in several areas of Greece, along with the diffusion of practices aimed at individual salvation such as the "Charon's fee." Coins are first found in burials at Corinth and other cities of Peloponnesus, and soon after in the rest of the Greek world including the Western colonies. The interpretation of this practice is not univocal, but

Tombs, Greek (Iron Age), Fig. 4 Poseidonia, cemetery of S. Venera. (From Cipriani 1989)

its first literary mention in the *Frogs* of Aristophanes (vv. 140 and 270) sounds like the parody of a custom that was well known to the audience and was perceived as alien from the traditional polis culture supported by the playwright.

The fourth century BCE is a period of transition and continuing crisis in the egalitarian principles of the classical polis, as demonstrated by the blooming of Athenian funerary sculpture. The elites compete in the construction of impressive family tomb enclosures, with the wall facing the road in fine ashlar masonry topped by stelai, other markers of different shape, and sculptures of sirens, lions, and dogs (Fig. 5).

Demetrius of Phaleron, governor of the city established by Cassander, reacted against these trends in his laws, probably influenced by ideas developed within the Peripatetic school. Theophrastus, the successor of Aristotle, is said to have explicitly forbidden any ostentation and unnecessary expense for his own burial (Diog. Laert. 5.53). Cicero (*de Leg*. 2.66) mentions the legislation of Demetrius against funerary luxury, which included restrictions on grave markers. The effect of these measures was apparently serious and may have been a major factor in the sudden crisis of Attic funerary sculpture, which did not recover visibly even after the end of his rule. The political and economic decline of the city probably also played a role. In the Hellenistic age, tomb enclosures were still in use, but were not as monumental as they used to be. In Hellenistic Attica, cremation became more frequent, but in general, burial customs did not change much. Among the new elements are gold wreaths that mark the heroic status of the dead, following the cultural trends of the period, and the diffusion of the "Charon's fee."

It is not in Athens but in other regions of the Hellenistic world that change in burial customs is most apparent, frequently influenced by trends that had developed outside the Greek world, in regions where Greek architecture and art had been adapted to meet the needs of very different societies (Fedak 1990).

In Macedonia, the aristocracy was buried in tombs marked by monumental mounds. The "heroic" ritual of cremation in metal urns (including gold and silver) probably alludes to the model of the Homeric poems, which were an integral part of the culture of the Macedonian elite. References to the "Homeric" customs were combined with eschatologic doctrines. The crater used as ash container in a tomb of Derveni is

decorated with scenes of complex Dionysiac symbology, and in the pyre debris were fragments of a papyrus containing a philosophical and religious treatise. Grave goods, when they have escaped looting, are very rich. The royal burials were accompanied by precious weapons, sets of silver and bronze vessels, and luxury items of all kinds. In the second half of the fourth century BCE, a specific tomb architecture developed in Macedonia, consisting of a mound covering a barrel-vaulted chamber with an architectural facade, and often enriched by wall paintings and sculptured stone beds and thrones (Fig. 6). This typology remained typical of Macedonia and had limited influence outside the kingdom, mostly in the bordering regions of Thrace, Epirus, and Thessaly, but it might have influenced the development of chamber tombs with architectural facade in other areas of the Hellenistic world.

Another influential tradition is that of the monumental tomb-heroon which had developed in Asia, where local elites had long adopted Greek architectural and stylistic models for original creations. An early example is the Monument of the Nereids at Xanthos in Lycia, a synthesis of the local tradition of tombs set at the top of a rectangular pillar, and Greek temple architecture and sculpture (Fig. 7). This trend is also seen in the Mausoleum of Halicarnassus, an awe-inspiring dynastic tomb decorated by Greek artists, built in the center of the new capital of the Hecatomnids, which would be the inescapable model and comparison for every later monumental tomb. Monuments influenced by the Mausoleum typology – stepped base, tall podium, temple-like upper level with free or engaged columns, pyramid with sculpture group at the top – are, for instance, the Lion tomb at Knidos and the mausoleum of Belevi. The tomb of Mausolos is also the ultimate model of the many types of towering tombs of the late Hellenistic period, such as the "Tomb of Theron" at Akragas and the tower tombs of Numidia. This typology was also successfully adopted in Roman Italy (Coarelli and Thébert 1988).

In Asia, another kind of tomb architecture developed as well, rock-cut chamber tombs with an architectural facade. They were already known

Tombs, Greek (Iron Age), Fig. 6 Facade of the Great Tomb of Leucadia. (From Charboneau et al. 1978)

Tombs, Greek (Iron Age), Fig. 7 Reconstruction of the Monument of the Nereids of Xanthos. (From Bianchi Bandinelli and Paribeni 1976)

in the Persian Empire, for instance, in the royal necropolis of Naqsh-e Rustem. Elements of Greek architecture are progressively incorporated and their facade assumes the appearance of a temple-like architecture. These tombs are found over a large part of Anatolia, where suitable rock formations exist. The most conspicuous ones are in Lycia and Pisidia.

The tombs of the Hellenistic kings are largely unknown. Our main source of information on most of them is short and not very informative literary accounts. The most famous, the tomb of Alexander the Great in Alexandria, was probably covered by a tumulus and, after the renovation decided by Ptolemy IV, was incorporated into a complex also including the graves of the Ptolemies. The most reliable image of the monument is probably preserved by the Mausoleum of Augustus, who visited the tomb of Alexander and regarded him as a great model. If the tomb in its last version was actually a round monument with cylindrical podium, it may be the model of a series of round monumental tombs found both in the Hellenistic and Roman world. Except for the tombs of Vergina and the tombs of the vassal kings of Rome of the latest Hellenistic period, the archaeological record is quite small. The mausoleum of Belevi near Ephesus, which closely follows the model of Halicarnassus, might originally have been planned for Lysimachus, and some believe it was used for Antiochus II.

In the Hellenistic period, there is tension between the egalitarian classical tradition, which was still a revered ideological model in the Greek cities, and the rise of a select elite who was eager to express its status. In the cities of Asia Minor, the upper classes frequently limit their funerary representation to family enclosures with stelai following the tradition of late classical Attic sculpture, with the addition of banquet scenes where the deceased is accompanied by family and servants. Representations and epitaphs focus on the traditional moral and civic virtues. Nonetheless, especially in the advanced Hellenistic period, urban elites are more and more willing to follow different models of funerary

Tombs, Greek (Iron Age), Fig. 8 Alexandria, tomb 1 of the necropolis of Mustafa Pasha. (From Charboneau et al. 1978)

self-representation. The members of the elite are celebrated in cemeteries as heroes and receive exceptional honors (statues and inscriptions) in the urban setting. In the ancient Spartan colony of Taras, a new funerary tradition develops, featuring tomb monuments with complex architectural and figural decoration, chamber tombs, and richer sets of grave goods, while the earlier system, based on very standardized tomb typology and grave goods, slowly disintegrates (Lippolis 1994). In the family tomb of Archokrates on Rhodes, the model of the rock-cut tomb with architectural facade is expanded to form a sort of two-level theatrical stage including altars, a design which fits in with the general "theatralization" of many aspects of public life in the Hellenistic cities. Another monument exemplary of the developing trends is the tomb of Charmylos on Kos, with a semi-subterranean chamber and a two-storey upper building, including an inscription which states that the monument and the surrounding garden are sacred to the Twelve Gods and Charmylos, "hero of the Charmyloi."

In Alexandria, a metropolis of recent foundation, funerary customs are as diverse as its population. One of the most common is secondary cremation in urns of different types, among which is a type of *hydria* (water pitcher) with painted decoration and sometimes inscriptions. Inhumation is also practiced. There are both individual tombs and chamber tombs of different sizes, the largest with open courtyard arranged as a pseudo-peristyle with architectural facades, on which burial chambers open (Fig. 8). These are also found in areas under Ptolemaic authority (Cyprus and Cyrene). Other collective tombs are long corridors with a number of small loculi closed by slabs. Sometimes, especially in the later Hellenistic period, decoration is a blend of Greek and Egyptian elements.

The great variability of funerary behaviors and strategies of the Hellenistic periods, with some general trends and a number of local traditions, is not interrupted by the Roman conquest. Instead, it becomes a major component of the funerary culture of the Roman world.

Key Issues/Current Debates

In the last half century, the funerary rituals and the attitude to death of Greek society have been investigated by scholars of different schools. Both the Anglo-American Post-Processual Archaeology and the French and Italian Anthropology of the Ancient World have strongly criticized the search for universally valid "laws" in the interpretation of funerary evidence attempted by Processual Archaeology in the 1960s and 1970s (e.g., Saxe 1970; Binford 1971). From different points of view, both schools have stressed the complexity

of the relationship between burial customs and society. Funerary rituals, of which burials are the main evidence available to us, are considered as a complex system of symbols, which does not constitute an immediate and reliable representation of the society that produced it. Rather, in those rituals, the image of that society is constructed and re-interpreted through the filter of ideology, using a specific code of symbols (e.g., Hodder 1984; D'Agostino 1985). As a result, funerary practices reflect the identity of the dead as it is constructed and represented by the living based on their vision of life, death, and the relationship between these two dimensions. Therefore, burials, rather than representing the individual, are a major source of information on the group he/she belonged to. The two schools also agree on the need for integration of the funerary record with all other categories of evidence available in order to place it in its specific context and decipher its language.

Burials have been largely used as a major source for the study of Greek society in all its phases, but have played an especially important role for its earliest period, when literary and epigraphic evidence is scanty and the non-funerary archaeological record very incomplete. As a result, burial analysis has been central in the recent debate on polis formation. Scholars have outlined general trends which can be interpreted as products of the developing collective ideology of the polis, such as the abandonment of ostentatious funerary practices and the transfer of the richest offerings from the grave to the common space of the sanctuary. These are very stimulating results, even though the model of classical polis should not be automatically applied to the study of much earlier periods when social dynamics were substantially different (Polignac 1996).

International Perspectives

In the field of the study of Greek burials, the contribution of the Anglo-Saxon school – where theoretical debate has developed especially within Prehistoric archaeology and anthropology – has concentrated especially on the study of the so-called Dark Age. The work of I. Morris on the cemeteries of Athens between Submycenaean and the Archaic age still follows some principles of the Processual approach, namely, the use of quantitative analysis, but takes into account the great problem of representativity of funerary evidence, at least from the demographic point of view. In some phases, the Athenian cemeteries present an acceptable representation neither of the demographic nor of the social structure of the population. This picture is explained by assuming that access to a formal burial was restricted, and in some periods, it became the exclusive privilege of the elite. Statistic methods have been used by J. Whitley in his study of the relationship between artisanal production and social level in the grave goods of the Athenian Dark Age (Whitley 1991). Both works have received appreciation and criticism, especially regarding the issue of quantitative analysis (Shanks 1991; D'Agostino and D'Onofrio 1993). The utility of such methods was defended by Morris, although his theoretical position has become closer to Post-processual archaeology (Morris 1992). The French and Italian schools have focused especially on the most complex and structured aspects of Greek funerary evidence, such as the iconography of figured monuments, and its relationship to literary sources (e.g., Gnoli and Vernant 1982). Other important academic traditions, such as the German one, have also produced valuable contributions – e.g., the excavation of the Kerameikos cemetery – but the theoretical aspect has been less developed, particularly in classical archaeology. However, in the last decades, German classical archaeology has been more active in this field, with a special interest in the potential of quantitative methods (e.g., Graepler 1997).

Future Directions

In light of the current views of the nature and limits of the evidence, the prevailing attitude today leans toward the selection of relatively homogeneous and sufficiently large samples, especially if the data of the cemeteries can be integrated with those from settlements, cult spaces, literary tradition, etc. The actual availability of such samples has been scarce, though.

A very few Greek cemeteries have been extensively excavated, and even fewer are those where adequate procedures have been used, the majority of information being from salvage excavations. Cases like the necropolis of Pantanello in the territory of Metaponto, fully and accurately excavated, studied, and published (Carter et al. 1998), are still exceptions. Therefore, the state of the evidence often obstructs the use of Greek funerary evidence to its full potential. The systematic diffusion of analysis of human skeletal remains – still not a standard practice – is likely to have a dramatic impact. Current debates on demographic trends and representativity of funerary evidence are in fact largely based on reasonable but arguable assumptions about the archaeological indicators of sex and age. It is also to be expected that the increase of quality and quantity of data produced by the advancement of methods of analysis and the refinement of theoretical background will make the issue of the use of quantitative methods especially relevant in the near future.

Tong Enzheng

Hongliang Lü
Department of Archaeology, Sichuan University, Chengdu, Sichuan, China

Basic Biographical Information

Tong Enzheng (1935–1997) was born in Hunan Province, Southern China, and obtained his BA and MA degrees in archeology from Sichuan University. He served as the Director of the University Museum and as Professor in the Department of History at Sichuan University. After moving to the United States in 1989, he held some short-term positions in a few universities in the United States with the last position being the Luther Gregg Sullivan Fellow of the Art Department at Wesleyan University. He passed away in 1997. Compared with the same generation of archeologists who were educated in China in the 1950s and 1960s, Tong achieved wide recognition due to his contributions to the archaeology of Southwest China. He also gained widespread recognition from the general public for his fiction novel and international fame for his involvements with western scholarship (Higham 2004; Von Falkenhausen 2014).

Major Accomplishments

In 1956, Tong was admitted to the history department of Sichuan University. In the summer of 1959, he followed his mentor Professor Feng Hanji, who obtained his PhD from University of Pennsylvania and founded archaeology at Sichuan University, to visit some Neolithic sites in the Three Georges area. After the trip, he wrote the novel *Ghost of the Ancient Fog* in a week and published it the next year. The novel was very popular in China at the time, and many young students learned and even admired the mysterious profession of "archeology" after reading the "fog of the ancient gorge."

During the "Cultural Revolution," Tong, as with most Chinese scholars, was unfairly treated, and his research was interrupted. In 1978, Tong directed the excavation of Karuo site, the first Neolithic site in Tibet, and published archaeological reports with detailed information on the data and provided more than 40 carbon-14 dates. This was the first time the ancient nature of human activities on the Tibetan Plateau was revealed, and Tong is considered the founder of Tibet's modern archeology.

In 1984, Tong served as professor of history and the curator of Sichuan University Museum, which was established by Americans in the 1920s. He launched a series of renewal projects for the university museum exhibition and contributed to the very good reputation of this museum. He also founded an academic journal *Southern Ethnoarchaeology* with a special focus on South China and Southeast Asia and published work from scholars based outside China, which afford a different scope compared with the main archaeological journals of China at that time.

At the Chinese Archeology Annual Conference held in Changsha in 1989, he was elected as an executive committee member of the Chinese Archeology Society. At the same time, he actively supported the Tiananmen student movement and attracted widespread attention. In the autumn of that year, he worried about political persecution because of his bitter experiences during the Cultural Revolution, and so he immigrated to the United States. During his stay in the United States, he worked in several universities and continued to publish academic papers in Chinese and English.

Professor Tong's academic career can be broadly divided into two stages, with the first stage from 1964 to 1979. During this time, his research emphasized the Ba-Shu origin of local cultures as well as their close relationship with cultural traits from the Central Plains, celebrating the unity of early Chinese culture. Tong saw these connections as extending from the Bronze Age all the way back to the Paleolithic, which is exactly what he himself later criticizes in his review of "Thirty Years of Chinese Archaeology" as the expression of nationalistic trends within Chinese Archaeology (Tong 1995).

The second and last 17 years began as he visited scholars in the United States in 1980 and before his death in 1997. During this period, his

attitude clearly underwent a major transformation, and he emphasized the importance of Southern China and assigned the area an independent role within the story of cultural origins. The changes described above are strongly related to the excavations at Karuo as well as his research trip to the United States. The encounter with Tibetan sites made him aware of the potential that the archaeological material of the border regions held. His research stays at Harvard, on the other hand, brought him into contact with the developments of western archaeological research which had continued from the 1930s (Lü and Zha, 2014).

The main hallmark of Tong Enzheng's scholarly work is the model of the crescent-shaped cultural-contact belt proposed in 1987 (Tong 1987). As a research notion, this cultural belt stretched from Northeast China and Korea along the Tibetan borderlands all the way to Yunnan and is still widely used and cited by present-day archaeologists working in Southwest China and beyond (Hein 2014). In recent years the rising interests in far-reaching exchange networks in global discourse, Tong's crescent-shaped cultural-contact belt has been widely cited in contemporary archaeology (Rawson 2017).

Topography of Rome

Jeffrey A. Becker
Department of Classical and Near Eastern Studies, Binghamton University – State University of New York, Binghamton, NY, USA

Introduction

Since the topography of Rome is concerned with a range of evidentiary material, any approach must involve a detailed consideration both of landscape and cultural-historical material. It is also notable that while the textual and epigraphic corpora are static (by virtue of being ancient), archaeological material continues to emerge that has direct bearing on the study of the city's topography, as clearly demonstrated by the excavations undertaken for the construction of Rome's newest metro train line (Egidi et al. 2010). Such new discoveries always carry with them the possibility of rewriting in substantial ways the topography of the city.

Definition

Derived from Greek, topography literally means "place writing" and has, since the Renaissance, constituted a major branch of Roman studies. The topography of the city of Rome has come to be defined as its own subdiscipline within the field of Roman archaeology. As such, this area, by necessity, combines the study of the ancient literary and epigraphic record with the archaeological, architectural, and spatial study of the ancient city. The field is narrow in its purview but extremely interdisciplinary and involves the study of the city from its origins in the early first millennium BCE to the present day. Advances in digital recording and modeling promise to expand the scope of topographic studies.

Key Issues and Current Debates

The Site of Rome

The site of Rome comprises a number of steep-sided hills with relatively flat tops and subsummits in the valley of the Tiber River. The Tiber and Rome are essentially linked in that not only did the river help determine the site ideal for settlement and facilitate commerce, but its frequent flooding also provided continual challenges for managing and mitigating flood waters and the damage they caused (Le Gall 1953; Aldrete 2007). From the early Iron Age onward, these hills served as *loci* for human settlement. The initial instances of settlement in the Tiber valley came in the form of small village communities, distinguished in the archaeological record by means of the remains of domestic architecture (often executed in wattle and daub) as well as by means of burials. Prominent villages have been identified on the Palatine, Capitoline, and Esquiline hills, mostly by means of the discovery of outlying necropoleis related thereto; of special note is the Iron Age cemetery known as the *Sepolcretum* (Gjerstad *Early Rome II* 1956). The swampy and seasonally flooded valley surrounded by these hills initially served as a necropolis (a key area of which is known as the *Sepolcretum*) but later came to be transformed into a central civic space, the *Forum Romanum* (Coarelli 1983–1992). This formerly inundated space was made usable by a massive program of artificial landfills; those anthropic layers have been sampled and studied by archaeologists, including Giacomo Boni, Einar Gjerstad, and, most recently, Albert Ammerman (Gjerstad *Early Rome III* 1960; Ammerman 1990, 1996), leading to the conclusion that the intentional landfill project occurred during the seventh and sixth centuries BCE.

Early and Archaic Rome

The origins of the settlement we call Rome date to the Iron Age when independent village-sized communities gradually coalesced into a state-level archaic community. The state formation mechanisms remain a matter of scholarly debate, although recent proposals include theories that point to the sharing of power, resources, and territory among tribal leaders (Terrenato 2011). The foundation story perpetuated in antiquity from at least the third century BCE onward focused on legendary figures such as Romulus, making him the responsible party for Rome's foundation (Liv. 1.9–13; Ovid *Fast*. 3.167–258; Ovid *Ars* 1.101–34; Plut. *Rom*. 14–15). While some scholars relegate Romulus to the mythical margin, others embrace his historicity wholeheartedly (Carandini 1997, 2007). By the sixth century BCE, Rome was a powerful state, and the elite architecture of the city – both private and sacred – had achieved monumentality, with the poliadic temple of the city (*Iuppiter Optimus Maximus*) being the largest structure of peninsular Italy.

Republican Rome

The Republican period (fifth through first centuries BCE) may be characterized by Rome's growth, both in terms of human population and architectural elaboration. Overall, however, the Republican period often witnessed haphazard architectural development as even extensive projects often represented the interests and prerogatives of individuals rather than the organized efforts of a centralized, state-level program. To this end leading aristocrats and those attempting

to climb the ladder of the social hierarchy utilized Rome's physical space as a mechanism of message making in order to solidify personal and familial status in full view of the Roman populace. Showy personal monuments such as the *fornix Fabianus* (Val. Max. 3.2.17; Appian, *BellCiv* 1.16), the *sepulcrum Scipionum* (Cic. *Tusc*. 1.13; Coarelli 1972), or the *columna rostrata* of Gaius Duilius (Plin. *HN* 34.20) all served to cue collective memory responses on the part of the Roman viewership, all the while appropriately celebrating the dedicant and/or honorand. The commemorative force of Republican public monuments would be reinforced by Augustan dedications like the *summi viri* in the Forum of Augustus (Suet. *Aug*. 31) and the *fasti triumphales* (Degrassi 1954).

During the Republican period (fifth through first centuries BCE), the topographic development of the city of Rome can perhaps best be described as haphazard, given that during some periods (e.g., the fifth century), there is evidence of very little construction, while at other points (e.g., second and first centuries), an enormous amount of development unfolded. Various scholars have been able to produce fairly comprehensive listings of information on monumental building in the Republican period based on the study of the textual and archaeological records (Crawford and Coarelli 1977; Ziółkowski 1992).

The middle of the first century BCE altered the arc of Rome's topographic growth forever as the political arena spawned a series of powerful, charismatic leaders who deftly employed programs of public construction as a means to bolster claims of political legitimacy and endear themselves to the urban populace. Among these men Pompey the Great, Julius Caesar, and Augustus are notable, not only in that their building programs were well conceived (and generally well received) but also in that they provided a paradigm on the basis of which later imperial patrons would operate. Augustus' building program, described in his own words in his list of achievements (*Res Gestae Divi Augusti*), transformed the city, particularly with respect to its public and sacred architecture (Favro 1996).

Imperial Rome

The imperial city from the time of Augustus onward may be best characterized by programs of civic architectural patronage interrupted by periodic unrest that generally disrupted the city's fabric and its upkeep. The aforementioned Augustan building program created a high standard of achievement, as the scope and scale of this program would have been difficult to equal. Augustan complexes transformed the city, totaling hundreds of thousands of square meters of built surface in the form of civic, sacred, and familial buildings, not to mention infrastructure projects. Augustus' successors struggled with their roles as civic patrons, although the emperor Claudius notably expanded the *pomerium* of the city (Tac. *Ann*. 12.23.2–24). The great fire of Rome under Nero (64 CE) radically altered the imperial city as, in wreaking havoc in the city center, it cleared a large amount of land that was subsequently reallocated for imperial usage, most famously in the construction of the Neronian palace park known as the *Domus Aurea* (Plin. *HN* 36.111; Suet. *Nero* 31; Ball 2003). While the Neronian fire and subsequent program were radical, it was short-lived as the subsequent building programs of the Flavian emperors reallocated a good deal of space for public usage, some in quite ostentatious ways – notably the Flavian Amphitheater, *Templum Pacis*, and the Baths of Titus (Suet. *Vesp*. 9; Darwall-Smith 1996). The Flavian program moved Rome into the second century CE in a stable and reasonably well-maintained state, in spite of a second major urban fire in 80 CE. The second century, Rome's most stable and prosperous period, saw Rome benefit directly from the patronage from a string of adoptive emperors stretching from Trajan to the Antonines. Key monumental programs like the Forum of Trajan and its honorific column articulated imperial ideology while taking full advantage of the tableaux of Rome's urban landscape (Packer 1997; Meneghini 2006). Even after the end of the Antonine line, the model of the ideologically informed imperial building program continued to inform the actions of subsequent emperors, even those who found themselves in office in turbulent and uncertain times in the later second and third

century CE (DeLaine 1997; Cooley 2007); this continuity is also evident in public, commemorative monuments such as the Decennalia monument (*CIL* 6.1204).

Rome in Late Antiquity

The arrival of the fourth century CE signaled significant changes for the city of Rome. Its diminishing strategic and economic importance spelled a gradual end to monumental public building programs, especially after Constantine I transferred the center of administration to the city of Constantinople in the eastern Mediterranean. Nevertheless, the first third of the century witnessed massive building at Rome, in part to help bolster Constantine's claim to power. These programs included the completion of projects belonging to his predecessors, notably the *Basilica Nova* (Pol. *Silv.* 545), alongside new programs such as the Arch of Constantine adjacent to the Flavian Amphitheater (*CIL* 6.1139). All the while Constantine was further altering Rome's topographic history by making way for Christianity in the public sphere, creating a series of Christian basilicae at the urban periphery; these sites would prove vital in Rome's history as their role as pilgrimage locales would continue to make Rome relevant even after the fall of the western empire. It seems that the notoriety of Rome's monuments continued in Late Antiquity, as demonstrated by notable episodes such as the visit of Constantius II to Rome in the middle of the fourth century when he stopped and marveled at the Forum of Trajan (Amm. Marc. 16.10.15). Ex novo construction tapered off after the fourth century; the last ancient monument to be erected in the Forum Romanum was the Column of Phocas in 608 CE. The ancient city, with greatly contracted population, gave way to the Medieval city, wherein ties to the past were broken and ancient monuments both reused and cannibalized (Arena et al. 2001–2004). It would take the force of the Renaissance to reestablish links to the past.

Organization of the Ancient City

The organization of the ancient city of Rome began with the demarcation of its ritual boundary (*pomerium*), an act ascribed to Romulus. The *pomerium* was an essential and inviolable aspect of an Italic city, as it regulated actions connected to the settlement and the conduct of business inside and outside the limit. The regulation against adult intramural burial stems from the pomerial tradition. The same traditional foundation story holds that Romulus created a settlement centered on the Palatine Hill, referred to as *Roma quadrata* (Tacitus *Ann*. 12.24). The meaning of this term remains obscure, and scholars debate whether it refers to the *pomerium* of early Rome or perhaps to an augural *templum* of sorts. The growing city of Rome was eventually divided into districts (*regiones*), an act ascribed to Servius Tullius (r. 578–535 BCE). These regions (*regiones quattuor*) were named *Suburana*, *Esquilina*, *Collina*, and *Palatina* (Varro *LL* 5.45; Liv. 1.43; Dion. Hal. *Ant. Rom*. 4.14) and may have corresponded to latent tribal or familial identities in the early city. The 14 Augustan regions established in 7 BCE replaced these Servian districts (Lott 2004). Each district was further subdivided into neighborhoods (*vici*). This redistricting reflected a need for increased administration in a city whose burgeoning population must have stressed the central authority's resources. These regions (and their neighborhoods) served as administrative districts in the city and also may be connected to the creation of shared, place-based memory and identity. The ancient boundaries of the districts can be determined, although not with absolute certainty, by means of the late antique documents known as *Curiosum et Notitia* (The *Curiosum* (Vat. Lat. 1984, 3321, 3227) and the *Notitia* (Vienna *Latinus* 162)). These documents could have originated from the city's administrative apparatus, as the office of the urban prefect (*praefectus urbanus*) was responsible for city administration (for the documents, see Arce 1999).

Rediscovering Rome's Topography

It is difficult to pinpoint the time at which an awareness of Rome's topography started, but Athanasius Kircher (vix. 1601/1602–1680), the Jesuit polymath, certainly had an awareness of spatial studies vis-à-vis the archaeology of Rome, as demonstrated by his mapping of the Roman

Campagna (Kircher 1671; Evans 2012). This topographic awareness involved the exploration of ruins in the landscape, exemplified by the aqueduct hunter (and Kircher's contemporary) Raffaello Fabretti (vix. 1618–1700) and followed on the previous century in which papal authority had begun to direct the creation of plans of the city of Rome that came to include ancient ruins. The landmark plan of Leonardo Bufalini, published in 1551 under Pope Julius III, included reconstructed plotting of the ruins in the city and represented a new milestone in the mapping of the ancient city (see edition of Bufalini and Ehrle 1911). Bufalini's work would inspire the great topographers Giambattista Nolli (vix. 1701–1756) and Giovanni Battista Piranesi (vix. 1720–1778). The former's *Pianta Grande di Roma* was engraved on 12 copper plates and published in 1748. It is simultaneously an aesthetic masterpiece and a hyper-detailed rendering of the city of Rome from a bird's-eye perspective. It, along with Bufalini's plan, proved fundamental, influencing Piranesi in his creation of his various views – both fantastical and realistic – of the ancient city. Piranesi published his *Pianta di Roma e del Campo Marzio* in 1774 and his *Le antichità romane* in 1784. These cartographers certainly changed popular perception of Rome and began the process of contextualizing her many ancient ruins; they perhaps also carry forward an ancient worldview that also had an awareness of the city's topography. The rediscovery of the first fragments of the Severan marble plan or *Forma Urbis Romae* in 1562 represents a major milestone in the study of Rome's topography (viz., Bellori 1673). Incised on marble slabs, the Severan plan presents a view of third-century CE Rome at a scale of 1:240 and provides many clues as to how the Romans conceived of their own world (Reynolds 1996; Trimble 2008). The plan has been studied exhaustively and continues to be the focus of ongoing digital scholarship undertaken by Stanford University (Carettoni 1960; Rodriguez Almeida 2002). It is not clear whether the Severan marble plan was meant to be a functional map or a decorative installation; what is clear is that the orientation of the city differs radically from the traditional north-oriented maps used today. The Severan marble plan served as an enormously important influence in the nineteenth century when the pioneering Roman archaeologist and topographer Rodolfo Lanciani (vix. 1845–1929) produced his own landmark *Forma Urbis Romae* between 1893 and 1901. Lanciani's map, divided into 46 sheets, presented the city at a scale of 1:1000 and plotted the ancient topographic features (in black ink) and the modern urban features (in red ink). The *Forma Urbis Romae* influenced the twentieth-century projects, including Italo Gismondi's famous model of Rome ("Il Plastico") produced for the Museo della Civiltà Romana from 1935 onward. That model, at a scale of 1:250, shows the city of Rome at the time of Constantine I in the fourth century CE. Lanciani's map remains an important source for topographic studies. Ongoing efforts to publish and digitize Lanciani's papers represent important assets in this field.

Topographic Scholarship

The early to middle twentieth century saw the creation of other major topographic compendia, including the *Topographical Dictionary of Ancient Rome* produced by S. B. Platner and T. Ashby (1929), that built on the major nineteenth-century scholarship (Jordan and Hülsen 1871–1907). In the *Fontes ad topographiam veteris urbis Romae pertinentes* (1952), G. Lugli collected the relevant literary and epigraphic resources for the study of the topography of the city of Rome; these were organized in eight volumes according to the Augustan regions of the city. The *Fontes* are essential for the study of the city and its monuments in that a great deal of the specific, place-based knowledge that survives is preserved in textual form. The later twentieth century saw the publication of two major topographic lexica, one for the city of Rome itself (Steinby 1993–2000; continuing now in supplementary volumes) and another for its *suburbium* or hinterland (La Regina 2001–2008). These lexica record entries for named topographic features; an additional companion series has now been established to document the history of urban excavation at Rome (e.g., Coarelli and Battaglini 2004; Coarelli 2006), which taken along with Lanciani's fieldwork diaries (Buonocore 1997–present) that

provide invaluable insight into the process by which the topography of the city has been explored and, in many cases, clarified. Also worthy of mention is a pictorial compendium to the topography of the city compiled by E. Nash using the photographic archive of the Deutsches Archäologische Institut (Nash 1962). These photographs remain an invaluable resource for the study of the city and its archaeological remains. Series of twentieth-century excavations have produced numerous site- and/or monument-based studies that are invaluable for the study of the city and, in particular, its topographic problems. The *Atlante di Roma antica* (Carandini 2012) draws on this wealth of excavation information and presents reconstructed plan and elevation views for the ancient city. Reconstruction has also been the focus of targeted topographical studies, notably in the work of James Packer who has published exhaustive studies of the Forum of Trajan and the Forum Romanum (Packer 1997; Gorski and Packer 2015).

International Perspectives and Future Directions

The study of Rome's topography has always been possessed of an international dimension, as the collaboration between English, German, and Italian scholars drove the major advances in Roman topographic scholarship during the nineteenth century. The Anglo-Italian connection in topographic studies remains strong, cemented in the early twentieth century by Thomas Ashby, then director of the British School at Rome. In the twenty-first century, topographic scholarship continues to benefit from international cooperation; this is particularly true as digital initiatives, including linked data projects, continue to widen the reach of traditional scholarship. Projects such as Stanford University's digitization of the fragments of the Severan marble plan and the digital modeling of Rome undertaken by the University of California, Los Angeles, and the University of Virginia demonstrate that not only is the study of Rome's topography international in nature but that digital applications represent an important new phase field in this field of archaeological scholarship. These visualization studies move the wealth of topographic information and site-based knowledge into the virtual space, allowing for various modeling exercises (e.g., Johanson 2009; Favro and Johanson 2010). Just as field archaeologists have embraced the power and potential of digital visualization approaches, so too has Roman topography. This is true not only in terms of 3D modeling but also in terms of employing geographic information systems (GIS) as an instrument for field recording and post-excavation analysis. The potential of light detection and ranging (LIDAR) is now emerging as a revolutionary tool for studying both landscape and topography; in the case of a built environment like Rome, LIDAR allows for the construction of digital elevation models (DEM) and digital terrain models (DTM) that allow for ancient landscapes to be reconstructed. While these technologies represent the lead edge of today's scholarship, their aim is perfectly in line with the long history of the study of Rome's topography, from the sculptors of the Severan marble plan; to Bufalini, Nolli, and Piranesi; to Lanciani and Gismondi; and to the scholars of today. Scholarship focused on visualizing the topography of the ancient city is steadily moving not only into more detailed reconstructive illustrations and graphics (e.g., Digitales Forum Romanum http://www.digitales-forum-romanum.de) but also into the realm of virtual and augmented reality (e.g., Rome Reborn).

Torii, Ryūzō

Naoko Matsumoto
Okayama University, Okayama, Japan

Basic Biographical Information

Ryuzo Torii (1870–1953) (Fig. 1) was a Japanese archaeologist and anthropologist. He was born in Tokushima in 1870, as the second son of a

T

Torii, Ryūzō, Fig. 1 Ryuzo Torii. (Photo courtesy of Tokushima Prefectural Torii Memorial Museum)

wealthy tobacco merchant. He left elementary school in the second grade and studied anthropology by himself. He became a member of the newly established Tokyo Anthropological Society when he was 16 years old and moved to Tokyo in 1892. He obtained a job organizing specimens for anthropology classes at the Tokyo Imperial University (now the University of Tokyo). Torii undertook his first fieldwork abroad at the Liaodong Peninsula in 1895 by chance and became fascinated with dolmens. This was the beginning of his tireless fieldwork in many areas of East Asia such as Taiwan, Siberia, northeast China, Mongol, the Chishima Islands, and Okinawa, conducted over 50 years. Torii married Kimiko in 1901. She often accompanied him on fieldwork and helped with his research.

Ryuzo Torii's academic career was not smooth. In 1905 he was appointed as a lecturer with the College of Science, Tokyo Imperial University. He obtained a doctorate degree in 1921 and became an associate professor at the Tokyo Imperial University in 1922, then professor at Kokugakuin University in 1923. However, he left his post at the Tokyo Imperial University and established a private anthropology research center in 1924. He was instrumental in the founding of Sophia University in Tokyo and became a professor and Head of the Department of Literature at this university in 1928. Torii quit teaching at Kokugakuin University in 1933. He was a visiting professor of Yanjing University in Beijing from 1939 to 1951 and continued active fieldwork in Shandong province in China. From 1941 to 1945 he was held under house arrest while the university was closed due to the Second World War. He died in Tokyo in 1953 at the age of 82.

Major Accomplishments

Ryuzo Torii is a unique figure in the history of Japanese archaeology and anthropology because of his lack of formal education. No one equals him in terms of the geographic range of his fieldwork and the width of his research interests, which included prehistoric archaeology, historic archaeology, physical anthropology, cultural anthropology, and folklore. Torii learned observation-centered research methods from Shogoro Tsuboi, who he respected as a teacher. Torii was quick to adopt the new technologies of the day, such as photography and the gramophone for recording audiovisual data. He took the first anthropological photos of the native people of Taiwan during his fieldwork there in 1896. The vast amounts of ethnographic record and photographs that he collected are regarded as important first-rate data today and are now housed in the National Museum of Ethnology, Japan.

Torii was interested in archaeology and carried out a number of excavations in Korea, China, Mongolia, and Japan. Through his archaeological research, he recognized close interregional relationships in prehistory and insisted that Japanese ancient culture had been under significant influence from the continent. In his fieldwork on the Chishima Islands, Torii found that the Chishima Ainu had been using stone tools and pottery and lived in pit houses until the recent past. He concluded that the Ainu people were descendants of the prehistoric inhabitants on the Japanese Archipelago. This hypothesis ran counter to the Koropokkur hypothesis advocated by Shogoro Tsuboi concerning indigenous inhabitants of

Japan. At the time of Torii's fieldwork, the Chishima Ainu were on the verge of ethnic extinction due to the emigration policy of the Japanese government. Torii felt deeply sorry for the situation and tried to do his best to record their life and culture. He took part in research in Korea from 1911 for the Japanese government after Japan's annexation of Korea in 1910 and conducted both ethnographic research and archaeological excavations of Stone Age sites and burial mounds. His archaeological collections are now stored at the University Museum, the University of Tokyo.

As with archaeologists from other parts of the world, Ryuzo Torii's work is inextricably linked to colonial processes. He has been criticized as an accomplice of Japan's colonialism. Although he did not intentionally support militaristic colonial policies, his fieldwork was inseparable from the colonization process. His theory that Japanese and Koreans are descended from the same ancestors was used to justify Japan's annexation of Korea.

Torrence, Robin

Sureyya H. Kose
Department of Chemistry, Curtin University, Perth, WA, Australia
Department of Earth and Planetary Sciences, Macquarie University, North Ryde, NSW, Australia

Basic Biographical Information

Robin Torrence is an archaeologist and a senior principal research scientist at the Australian Museum, Sydney, Australia. She grew up in Illinois, USA, and graduated magna cum laude from Bryn Mawr College, Pennsylvania, gaining an B.A. in 1971. She completed a Master's degree (1974) and a Ph.D. (1981) in Anthropology at the University of New Mexico, USA. Between the years of 1969 and 2013, she has been involved in extensive archaeological field and laboratory and museum projects in the USA, Europe, Papua New Guinea, and Far East Russia. More recently, she has turned her attention to the archaeology of ethnographic museum collections.

Early in her career Dr. Torrence undertook graduate teaching roles in the University of New Mexico and later held academic appointments at several universities in the USA, Great Britain, and Australia as lecturer and associate professor. While at the University of Sheffield, UK, she participated in a field school in excavation and surveying at Roystone Grange, Derbyshire. During her career she has taught a wide range of subjects concerning archaeological theory and practice including practical courses in lithics, quantitative data analysis, and computing in archaeology and theoretical subjects predominantly in anthropology, exchange, hunter-gatherer studies, and stone tool technology.

Current research interests include method and theory in lithic studies, archaeology of the Pacific region, prehistoric exchange (with special reference to obsidian), role of natural disasters and risk

avoidance in long-term history, Indigenous agency within colonial societies (with special reference to Papua New Guinea), and complexity and diversity of material culture and hunter-gatherers.

Major Accomplishments

Throughout her career, Dr. Torrence has been on national committees such as the Pompeii Committee, UK (1979); Executive Committee, Theoretical Archaeology Group, UK (1979–1989); National Committee for the International Union of Pre- and Proto-historic Sciences, London (1982–1986); Committee on Archaeology and Anthropology, Royal Anthropological Institute, London (1982–1989); Council, Royal Anthropological Institute, London (1983–1986); Institute of Field Archaeology, Committee on Theoretical Archaeology (1984–1985); and Steering Committee, Southampton-York Archaeological Simulation System, Science Research Council (1987–1988).

Dr. Torrence has been on editorial boards of major peer-reviewed journals such as *Man* (1983–1989), the *Journal of Mediterranean Archaeology* (1987–1991), *Bulletin of the Indo-Pacific Prehistory Association* (2007–2009), and *Museum Anthropology* (2009–2012), with current editorial board appointments in *Archaeology in Oceania*, *Lithic Technology*, *Journal of Field Archaeology*, *Australian Archaeology*, and *Heritage Management*. She is a senior editor of the *Journal of Archaeological Science*.

From the years 1973 to 2012, Dr. Torrence has published 1 single authored and 12 edited books and over 100 articles in archaeology and anthropology. She was the founder and chairperson of the Ancient Starch Research Group (1998–2000) and was the treasurer of the World Archaeological Congress (1995–2003).

She has had a key role in developing new methods for studying trade, stone tool use, and ancient starch analysis and currently conducts interdisciplinary research into understanding changes in the nature of western Pacific societies over the past 50,000 years.

Tourism and Archaeological Education

Uzi Baram
Division of Social Sciences, New College of Florida, Sarasota, FL, USA

Introduction

Visiting the ancient ruins of southern Europe and the eastern Mediterranean was a hallmark of the Grand Tour, the convention of travel in sixteenth- through nineteenth-century Western Europe. The children of the elite visited Rome, Athens, the Pyramids of Giza, and, if possible, Jerusalem to see antiquity, exemplified by archaeological remains. The goal was social polish, with education being the focus of the experience for when these travelers returned to their homes for launching their careers. Mark Twain, whose mid-nineteenth-century travels from the United States to the Mediterranean came as travel gave way to tourism, expressed the educational aspect of such visitations with his famous remark (1869: 650): "Travel is fatal to prejudice, bigotry, and narrow-mindedness." Traveling to see the past, particularly a past understood as part of one's heritage, is an ideological endeavor that can encourage xenophobia or cosmopolitanism, be driven by education or entertainment (Baram 2018); today traveling is encompassed within tourism. According to the World Tourism and Travel Council (2018), tourism is one of the world's largest

economic sectors, more than 10% of global GDP and nearly 10% of total employment. The intersection of tourism and heritage, particularly the representations of the archaeological past in the form of educational programs, is developing into challenging ethical concerns for archaeologists.

Definition

The United Nations World Tourism Organization (2018) defines tourism in terms of travel and visitors. The anthropologist Chambers refines (2010: 6) the term as "any kind of travel activity that includes the self-conscious experience of another place." A major focus for tourist experiences is heritage, the cultural and historical aspects presented for the present, and the major component of heritage is the finds and findings from archaeological research. Interpreting the archaeological materials for the public, especially those identifiable as tourists, is an ethical concern as well as an educational imperative.

Many archaeologists have recognized the importance and potential of educating the public about the past, particularly the lessons that come from humanity's common origins. In the mid-twentieth century, Grahame Clark (1943: 113) wrote: "What is needed above all is an overriding sense of human solidarity such as can come only from consciousness of common origins. Divided we fall victims to tribal leaders: united we may yet move forward to a life of elementary decency." Similarly Glyn Daniel and Colin Renfrew (1988: 52) stated in *The Idea of Prehistory*: "Whether we are Americans, Russians, Indians, or Chinese we share a universal human historical heritage. I do not pretend, or imagine, that a recognition of this fact will alter present-day differences but if people really had an awareness of human history it should put present-day differences in a different perspective and one that made for tolerance." The theme of the past as a resource for educating on human potential is expanded upon in Robert MacKenzie and Peter Stone (1990) *The Excluded Past: Archaeology in Education* and more examples are found in *The Presented Past: Heritage, Museums and Education* edited by B. L. Molyneaux and P. G. Stone (1994). Both are volumes in One World Archaeology, the World Archaeology Congress publication series. The idealism has been sustained by archaeologists around the world, with the sense that sharing the insights of archaeology can contribute to coexistence and peace, a sense of community, and ecological awareness.

With the broad goals clear, some archaeologists have moved to provide instruction to meet educational goals using either archaeology as excavation, as material culture, or as history to convey the findings of the field (Fig. 1). The main focus in the USA has been educating to prevent looting and vandalism, to protect the past for the future. A key volume for archaeology and education is *The Archaeology Education Handbook: Sharing the Past with Kids* by Karolyn Smardz and Shelley Smith (2000). The handbook offered examples and suggestions for developing a subfield of archaeological education, stressing the need to work with teachers. As standardized testing became policy across the USA, meeting grade-level standards became a central concern for archaeologists wanting to offer opportunities for children. Practical examples can now be found online, for instance, the Society for American Archaeology (SAA) has an online resource titled *Education and Outreach – Resources for Archaeologists* with multiple links to resources and the Florida Public Archaeology Network has lesson plans available on its website. A new academic journal began in 2017 *The Journal of Archaeology and Education* is a forum for educators to share experiences and research as well as wrestle with theoretical concerns.

Archaeological education for children has a clear sense that the rising generation will be intrigued and engaged with the materials and will retain those perspectives when they reach adulthood. Since, in the early twenty-first century, we seem to have reached what Neil Postman's (1982) thought would happen to the line between childhood and adulthood: it has been erased by new technologies. Programs that successfully engage and educate children are rarely limited to children; their guardians/parents may be as interested. And with the goal of sharing the insights

Tourism and Archaeological Education, Fig. 1 Elementary school student using an atlatl during an educational outreach program to experience ancient lifeways

and information, to teach respect for the archaeological record and encourage the recognition of a common humanity, audiences can be, even should be, broad. One of the productive avenues for attracting a broad audience is tourism, in the sense of the creation of marketing and infrastructure for visiting a place for an experience; archaeology fits heritage tourism, a niche within tourism that many associate with time travel. Experiencing the materiality of the past is as much about difference as traveling to geographically distant places. That sense of difference becomes a productive avenue for educating a broad audience, including children. As with much of the research on tourism, the divide between tourism as educational opportunity and tourism as accelerating political economic inequalities marks assessments of trends and programs.

Key Issues/Current Debates/Examples

Archaeological education faces the intersection of the two terms that make up the concept. For some, the focus is educating the public on archaeology, archaeological investigations, and the science of archaeological findings. The representations can be performative – a live lecture or video of a presentation, signs explaining the excavations and its results, and published through a wide range of possibilities from books to artwork. The alternative is employing archaeological techniques and methods to convey how the science of archaeology work and the insights into material culture (making objects using preindustrial technology), social change, and the history for a particular place at a specific epoch or historical moment. Archaeology is used as a means to convey lessons about inquiry and research. The divide plays out in archaeological education for tourism.

Anthropological studies around the world have described the dichotomies involved with tourism, including heritage tourism that focuses on archaeology. Tourism encourages understanding of human differences, the human past, and a common human heritage. Tourism accelerates social inequalities. Both dynamics are occurring concurrently in today's world.

Visiting archaeological sites is educational. Sustaining the interest of tourists requires entertainment. Debates over tourism to archaeological sites revolve around the tension between education and entertainment, or as an early observer of the trend Mike Wallace (1996) noted: edutainment.

The question of edutainment haunts the range of possibilities for educating on the past. Some programs teach archaeological techniques. In the 1960s, Yigael Yadin asked for volunteers to come

to excavate the challenging location of Masada for its Roman-era fortress; in his popular book on the project, Yadin (1966) expressed delight that 300 volunteers, at a time, worked on the excavations. The project received volunteer labor and those individuals gained experiences; archaeological expeditions continue to provide fieldwork opportunities for volunteers and for students to gain academic credit and experiences. Such research-oriented projects are education-based and several organizations continue encouraging informed participation in archaeological projects, for instance, at the place-centered Crow Canyon Archaeological Center in Colorado, USA, or the Archaeological Conservancy with its tours of archaeological locations. In 1978, D. V Clarke questioned the effectiveness of excavations, focused on volunteers at Kara Brae, Orkney, Scotland; the unevenness of recovery of lithics led to a plea for evaluation. The scale of volunteers working on archaeological projects has increased, whether as volunteers for research or as entertainment, yet as Kaminski et al. (2011) state, the implications for archaeology are important. Some volunteer opportunities are focused on local communities (Baram and Austin 2011), but with voluntourism being a growing niche endeavor within tourism, especially the dynamics that require the participants to pay for the opportunity to volunteer, new implications need to be considered and assessed. One implications are programs where tourists can experience excavations as Dig for a Day: at Tel Maresha, in Israel, according to the Archaeological Seminars website states, thousands have excavated the Hellenistic remains at Beit Guvrin and Texas, in the United States, has multiple locations where the public can, as their webpages state: dig for arrowheads. The expansion of such edutainment programs is a challenge to professional ethics.

Travelers on the Grand Tour took relics; tourists expect souvenirs. Gift shops can offer reproductions that are educational – the reminder of something seen, the opportunity to examine an artifact replica closely at home, and the opportunity to spark memories through an object are the positive aspects of souvenirs. The replica can be local crafts or products of the neoliberal global economy, most likely as Made in China and be a caricature of heritage (Fig. 2). When the replica is

Tourism and Archaeological Education, Fig. 2 Items in a gift shop in Georgia, USA

educational, the want for the authentic can encourage other visitors to seek out artifact and facilitate the antiquities trade. Beyond souvenirs, to meet interest in remembrances of tourist experiences more places are offering not only gift shops but also spots for selfies, photographs of the visitor at the place in an iconic manner.

Finally, in today's experience economy the stories gained from docents can be the value sought and received by the tourist. The line between responsibility for accurate and engaging information and capturing and sustaining visitors' interests in the past raises ethical concerns. The USA National Park Service follows Freeman Tilden's (1957) call to inspire visitors, to express more than facts, and to create memorable stories that the visitor can share.

Future Directions

Some archaeologists use insights from research to inspire knowledge of a place or material culture, to teach history through displays of finds and findings. There is a wide range of displays, from the physical to the virtual, with increasing opportunities in the digital realm for interactive learning experiences. Some use archaeology to teach ecology, hands-on activities that give participants a sense of the place, connecting present and past. The divide between historical particularly and creating connections across time is a challenge for continuing consideration in archaeological education, especially for visitors to a location.

Archaeologists are developing specialized skill sets for presenting information to public audiences including tourists even as archaeological discoveries have a long tradition of being put on display. Where once the visitation to an archaeological site versus a museum could be differentiated, contemporary opportunities allow the line to be blurred through digital technologies as well as archaeological sites reproduced in museums and museums built at archaeological sites. Herreman (1998) recognized tourism transforms museums and museum professionals have to be up for the challenges, a useful lesson for archaeological education programs and continuing efforts by archaeologists at public outreach and community engagement.

For tourists, archaeological educational programs are opportunities to receive special access to or insights into sites, led by a scholar or an interpreter skilled with engaging the public. The special access can cause tensions, as Bruner (1996) described for the Elmina Castle in Ghana. The national government saw the historic site as a draw for tourism, particularly African-American tourists interested in the slave trade. Tourism would bring economic development while the tourists would engage the location as an educational experience with the emotional connection to the Door of No Return. For the Ghanaians, the long history for the place became essentialized to represent one, significant epoch. But the dynamic go beyond simplification of history into heritage. A sign at Elmina Castle stated that the area is for tourists only (Bruner 1996:298); the separation is ideological and physical.

Signage is the materialization of information for an archaeological site. Travelers on the Grand Tour would bring back relics and other objects for displays in their homes and such cabinets of curiosities were one forerunner of museums. Museums have a long tradition of having labels for their collections, information on the object displayed. Labeling features on an archaeological site is edifying, providing basic information on architecture and time period so that the visitor to the site can make sure of the stones and other remains (Fig. 3). As heritage tourism increases, more interpretative signs are being placed by archaeological sites in order to inspire interest (Fig. 4) and others are creative, meant to encourage curiosity about the archaeological research. And similar to the dynamics for tourism, the shift from education to entertainment is seen in signs. Visitors notice and read signage and even fake signs, such as Walt Disney World's recently opened Disney Springs, a shopping complex that has signs for a town that never existed (Fig. 5). Signage can be informative, engaging, and misleading and a matter of ethics for the presentation of the past for the present. Who creates and maintains the signage is an ethical matter for those committed to archaeological education in an age of expanding tourism.

Tourism and Archaeological Education, Fig. 3 Label for altar at San Gervasio ruins on Cozumel, Mexico

Tourism and Archaeological Education, Fig. 4 Heritage interpretative sign for Fort Mosé Historic State Site, USA

T

Tourism and Archaeological Education, Fig. 5 Disney springs, Orlando, Florida, USA

Archaeologists will continue to use the opportunities provided by tourism, with the potential for using the insights from the past to encourage coexistence and peace, as well as grapple with the dynamics stimulated by neoliberal globalization that commodifies and simplifies scholarship to provide consumerist opportunities for experiences and entertainment. In both theory and practice, the challenges of tourism for archaeological education are part of the process to convey the archaeological past to the present in effective, engaging, and meaningful ways.

Tourism, Archaeology, and Ethics: A Case Study in the Rupununi Region of Guyana

Jared Bowers
International Centre for Cultural and Heritage Studies, Newcastle University, Newcastle Upon Tyne, UK

Introduction and Definition

Ethics is a feature found in seemingly every discussable topic. It guides moral decision-making, informs strategic thought, and ultimately influences human behavior. Ethics is based upon the principle that individuals are members of a community, cogs in a much larger machine. There is hence a fundamental responsibility for individual motives to align with the needs of the larger community. This entry briefly elaborates on this concept with a particular focus on the ethical relationship between tourism and archaeology. Key themes that are considered include the respective ethical frameworks for tourism and archaeology and the relationship between their unification. Also examined is how this relationship can effectively be developed within an emerging tourism and understudied archaeological site: the Rupununi region of Guyana.

Key Issues/Current Debates/Future Directions/Examples

Ethics, Tourism, and Sustainability

As one of the world's largest industries, tourism involves much of the world's natural and cultural heritage resources. In 2010 alone, there were 935 million international tourism arrivals who spent an estimated US$ 919 billion worldwide (UNWTO 2011). Within an industry of this magnitude, there has been, and continues to be, a plethora of impacts on the local economy, communities, and natural and cultural heritage. Moreover, there exists a multitude of stakeholders with their own varied interests. Thus, there is an essential need to consider the role of ethics in tourism development (Payne and Dimanche 1996: 998; Malloy and Fennell 1998: 454). Yet, what ethical framework can be used that universally appeals to all tourism stakeholders? How do you balance the interests of one group with another? Ultimately, it is argued that these questions can be answered by referring back to the well-established notion of sustainability.

Defining sustainability has been regarded as an ambiguous process and varied in relation to the context (Shearman 1990: 1). However, Shearman (1990: 2–3) asserts that the contextual definition is irrelevant and the "meaning of sustainability is far from ambiguous." Indeed, the concept, quite simply, revolves around techniques that utilize resources in a manner which does not deplete or

permanently damage them. It is a concept which has existed for hundreds, if not thousands, of years and goes beyond the current exploitation of its namesake. Moreover, sustainability does not relate specifically to the natural environment, society, or corporate economic frameworks – instead it is a concept which is broad enough to be applicable to all. But why is sustainability important? What are the ethical reasons for wanting to use sustainable management structures? Ultimately, this desire for sustainability refers to the prolonged positive impacts for present and future anthropocentric and biocentric systems (Shearman 1990: 5).

Sustainability is in alignment with an ethical framework known as teleology. Within this system of ethical thought, moral conduct is determined by the end result (Malloy and Fennell 1998: 455). Teleology is guided by two governing "schools of thought" – hedonism and utilitarianism (Malloy and Fennell 1998: 455). Both of these disciplines are concerned with maximizing benefits and minimizing negative impacts – delivering the notion of "good." However, while hedonism focuses on individual priorities, utilitarianism deals with the "greatest good for the greatest number" (Malloy and Fennell 1998: 455). Sustainability is a pursued end result because it endeavors for the prolonged life of resources for present and future generations – the greatest good for the greatest number.

Teleology does not argue that one should simply "be good" and follow ethical rules as the concept of deontology does. Instead, teleology emphasizes that a desired outcome (such as sustainability) is better for all of mankind. Similarly, American philosopher Henry David Thoreau (1817–1862) once wrote that people should "be not simply good, be good for something." In this manner, teleological utilitarianism demonstrates why tourism resources should be safeguarded and used ethically by all generations. Furthermore, tourism possesses several stakeholders whose interest should be valued equally, and teleology presents a framework to accomplish this task. The following paragraphs discuss the role and placement of archaeological resources in alignment with this ethical tourism framework.

Archaeological Resource Education and Preservation

Archaeology also utilizes a teleological framework but positions this ethical structure with a focus on the greatest good for the archaeological record. Indeed, Lynott (1997: 593–594) argues that first and foremost, archaeologists should promote "stewardship" of archaeological resources to improve their understanding and preservation for future generations. However, he (Lynott 1997: 593–594) also asserts that within the need to conserve and safeguard the record, there is a dual need to use it for educational and interpretation purposes (see also Meskell 2000: 161). It is in this capacity where archaeological resources can be a significant and viable tourism product.

Cultural heritage tourism is one of the fastest growing sectors in the tourism industry and encompasses archaeotourism, a form of tourism focusing on archaeological resources (du Cros 2001: 165; Wurz and van der Merwe 2005: 10; Levine et al. 2005: 401; Karki et al. 2006: 47; Ramsey and Everitt 2008: 909). However, archaeological resources are unique and "highly sensitive" to tourism use and consequently require vigilant preservation (Wurz and van der Merwe 2005: 10; Ramsey and Everitt 2008: 913). The needs of such a growing tourism sector hence require to be balanced with the management of the archaeological record (Wurz and van der Merwe 2005: 11). Whereas equality is usually promoted among stakeholders in sustainable tourism frameworks, Wurz and van der Merwe (2005: 11) argue that when archaeological resources are involved, the record's preservation must always receive priority over tourism objectives. This is justified by the fragile nature of archaeological assets and their importance in representing the heritage of living communities for present and future generations (du Cros 2001: 166; Atalay 2006: 283).

This view echoes the same principles found in a teleological framework for tourism. There is an ethical obligation for archaeologists to protect the record for all generations to benefit and learn from, yet this can often conflict with tourism priorities. However, the need to ensure the "greatest good for the greatest number" has superiority and gives archaeologists the ethical "right"

to shelter heritage resources away from tourism development. The sustainable use of archaeological resources is still the targeted end result, and the manner in which this target is achieved is irrelevant (du Cros 2001: 166). Archaeologists do have a responsibility to present their findings to the public today, but they have an equally important responsibility to safeguard material heritage for future generations. In essence, archaeologists should work congruently with sustainable tourism frameworks in order to actively contribute to the preservation of heritage resources while working to interpret their meaning for visitors (Wurz and van der Merwe 2005: 11). This next section examines a contextual location where tourism development is increasing in an area where there are significant but unknown archaeological resources.

Finding the Right Way Forward: Archaeotourism in the Rupununi

The Rupununi is a vast tract of land in central Guyana. The landscape is composed of naturally occurring savannah wetlands and tropical rainforests, and the region has been largely inaccessible until recently. The small population of 16,000 inhabitants is predominantly comprised of three main indigenous groups who occupy most of the land: the Makushi in the north and the Wapishana and Wai-Wai in the south (Nycander et al. 2010: 13). Various archaeological studies have proven that Amerindians have been living in the region for over 7,000 years, initially as hunter gatherers with land cultivation occurring around 2,000 BCE (Williams 2003: 3–11).

The Rupununi is rich in both natural and cultural heritage resources. As a result, several communities have been increasingly developing tourism programs as their primary source of revenue in an area struggling with diversifying its economic activity. However, with one to two thousand visitors a year, tourism is still in its infancy and remains a low-impact activity. Local cultural heritage used for tourism includes a number of archaeological resources. These resources are primarily comprised of pictographs and petroglyphs (Fig. 1) but also include stone tools, chipping stations, rock circles, and polissoirs (Williams 1979).

Tourism, Archaeology, and Ethics: A Case Study in the Rupununi Region of Guyana, Fig. 1 Amerindian petroglyphs. (Photo by Jared Bowers)

Plew (2004: 12) revealed that the Rupununi is host to a wealth of archaeological resources which remain "relatively unexplored." Indigenous Amerindian communities have occupied and used both the savannah and rainforest environments for thousands of years. An exploration of the archaeological record in the region could consequently be useful in addressing significant research questions in northeastern South America (Plew 2004: 7). These questions refer to topics such as ritual sites, food procurement, and hunting strategies among the Rupununi's transient communities. Long-term environmental patterns inside the region could also be documented (Plew 2004: 7). Despite remaining mostly unexplored, the utilization of these archaeological resources for tourism is currently on the increase. This underlines the need for an effective management structure.

As both tourism and archaeology seek to progress their development in the region, the use of a teleological framework will become increasingly important. Within this framework, defining how to simultaneously safeguard and use archaeological resources for economic gain will be the primary focus. However, the guiding principle should be how to use this resource for the greatest good for the greatest number. It is essential that management figures establish both sustainable visitation guidelines such as limits of acceptable change and maximum visitor cap and research tactics with, for instance, community archaeology and public participation. These methods will ensure that the resource remains protected for

present and future generations (Marshall 2002: 218; Wurz and van der Merwe 2005: 15).

Conclusion

This entry set out to gain an understanding on the ethical relationship between tourism and archaeology. Individual ethical frameworks for tourism and archaeology were explored, as well as how the unification of both disciplines can be used to achieve a similar ethical goal. This ethical goal is the ingrained concept of sustainability and can be reached through a teleological system of thought. This entry briefly investigated this relationship in the Rupununi region of Guyana and stressed the importance for sustainability in the education and preservation of archaeological resources. The author argues that it is essential for all future use of archaeological resources for tourism to consider and prioritize sustainability – in order to ensure that all are able to experience our cultural heritage.

Tracking in Caves: Indigenous Ichnology

Andreas Pastoors[1] and Tilman Lenssen-Erz[2]
[1]FAU Universität Erlangen-Nürnberg, Erlangen, Germany
[2]African Archaeology, University of Cologne, Cologne, Germany

Introduction

In prehistoric research the importance of the archaeological as well as the natural context of

rock art has been underestimated over long periods. Only recently has research begun to take this context into focus for documentation, analysis, interpretation, and understanding. Human footprints are most prominent among the long-time under-researched features of the context of cave art. In order to compensate for this neglect, a special research program has focused on the merging of indigenous knowledge and Western archaeological science for the benefit of both sides. With the expert assistance of indigenous San hunters from the Namibian Kalahari, this "Tracking in Caves" project endeavored to better understand aspects of the Upper Paleolithic human behavior, traces of which are preserved in footprints in painted caves in southern France. The three professional indigenous trackers were invited to Europe and conducted in-depth research in the caves Niaux, Pech Merle, Fontanet, Tuc d'Audoubert, and Aldène (Fig. 1).

The preservation of footprints from the Pleistocene depends on advantageous taphonomic circumstances and on careful treatment of the caves after modern rediscovery. Accordingly Pech Merle has less than 20 footprints, but the other caves each have at least several dozen and some several hundred. In Aldène they were left behind by visitors during the Mesolithic, Niaux is hardly dated, and all others are of Upper Paleolithic origin.

The documentation of the interpretations of the indigenous ichnologists is indispensable, but it is no less important to cross-check the results obtained with the results of the studies of Western sciences. The circumstance that the results of indigenous ichnologists are difficult to evaluate does not imply that they are worthless assumptions. They have to be verified or falsified with quantitative analyses and integrated into the discussion of prehistoric human footprints.

Definition

Tracking, or reading tracks, is a special skill that is a precondition for human hunting and therefore may be considered "the beginning of science" (Liebenberg 1990). As such, it is related to ichnology, the science of tracks and traces, which originally was mainly occupied with fossil tracks (such as of dinosaurs) but since the discovery of the earliest hominid footprints in Laetoli (Tanzania) has also turned to humans (Lockley 1999). In current research of prehistoric human footprints, Western science reveals essentially two approaches: first, footprint outline and landmark-based geometric-morphometric analyses (Bennett et al. 2009; Bennett et al. 2016) and, second, pixel-based quantitative analysis of the whole foot pressure (Crompton et al. 2011).

In pre-industrial societies of hunter-gatherers and herders, mastery of track reading is an existential necessity. It is being learned from early childhood onward, requiring lifelong learning and constant practice. Therefore tracking is also "tacit knowledge" (Polanyi 1966) that cannot be expressed in words but is acquired through experience and direct exposure to the object of

Tracking in Caves: Indigenous Ichnology, Fig. 1 Reading of human footprints in Niaux by Kxunta and Thao. (Photo Tracking in Caves)

learning. The indigenous ichnology of hunter-gatherers is linked to Western ichnology in that it implies inductive and deductive as well as abductive methods (Liebenberg 1990). Moreover, for the differentiation of, e.g., male and female footprints, trackers assess the same markers on a foot as orthopedists.

Presently indigenous ichnology has a much finer resolution of tracks than modern morphometric methods since trackers are normally able to determine from a footprint the sex and the approximate age class of a person, where the latter is not a factor of body height but based on overall foot proportions and traces of aging. It also means that they are able to follow the tracks of an individual – be that person, game, or herd – under changing soil conditions and even if mixed with imprints of other individuals of the same species.

This capability was the basis for analyses of human footprints in the Paleolithic caves.

The results of the certified indigenous ichnologists compiled in the course of the various studies are surprisingly detailed and precise, and they go beyond the results produced by Western science. This fact is perceived differently by the public. If exposed to the results, one part of the public shows scientific curiosity, wishing to learn more about the capabilities of indigenous ichnologists and to verify or falsify the results through their own investigations. Others, however, show great skepticism to the extent of rejection. Such rejection does not seem appropriate without empirical falsifications, because indigenous ichnologists have verified skills in reading tracks. Strictly speaking, their methodological approach is not so alien to Western scientific approaches. Even though Erwin Panofsky's iconographic interpretation method refers to images, there are parallels between reading tracks and interpreting images. According to Panofsky, in the case of a natural subject as the object of interpretation, a pre-iconographic description of the motifs takes first place (Panofsky 1962). Practical experience (familiarity with objects and phenomena) is an absolute prerequisite for a successful description, from which a positive correlation between experience and descriptive accuracy can be derived. In the event that the spectrum of personal experience is not sufficient, this spectrum must be extended by consulting publications or experts. Practical experience, in turn, helps to determine which publication or professional is to be consulted (Panofsky 1962: 9). This practical experience results not least from personal experiences in the world in which we live and which "provides the ground for all cognition and for all scientific purpose" (Husserl 1939: 38). The concept of the "lifeworld" that is evoked here describes the realm of reality in which every human being inevitably participates (Schutz and Luckmann 1973). With the fundamental trust that the world has not changed since the production of the imprints or the making of the image to the extent that trees have always been trees and birds have always been birds, one's own practical experience is valid regardless of the respective cultural attributions to trees and birds. The reference to personal experiences and personal exposure to the object of description is at the same time a reference to the fact that "tacit knowledge" (Polanyi 1966) is also required to a considerable extent. These are knowledge and cognitive possibilities that cannot be made explicit but rather are specifically available to each individual through an embodiment of experience.

In archaeology, already at the beginning of the twentieth century, a certain helplessness and a lack of experience with regard to the reading of tracks in the interpretations of prehistoric footprints by Western scientists became apparent. Thus, not the recognition of a specific sequence of footprints was responsible for the interpretation as ritual dance, but the transfer of the generally perceived ritual status of the surrounding cave to the footprints. At this point, a lack of experience in reading tracks was masked by the corrective principle of interpreting cultural-historical processes. Not only the lack of practical experience in reading tracks proves to be problematic but also the existence of methodological limits of modern analytical procedures. This is particularly evident in the difficulty of making the sequence of steps of one and the same person morphometrically visible, even though it is obviously from one person.

Against the background of interpretations favoring ritual activities, the results of the

indigenous ichnologists appear unspectacular. But they fill a vacuum of description with content. An accumulation of footprints on a spatially limited area seems like a chaotic mixture. This confusion dissolves when the indigenous ichnologists combine footprints into sequences of steps of single individuals. If only those footprints are taken into account that the indigenous ichnologists can use to determine demographic data, rather many footprints have to be ignored since variable quantities cannot be assigned to sex and age class. The demographic data is ultimately established by using morpho-classificatory factors, which are essentially based on the same features that Western science also uses.

Contextual information is also included in the track data collection: the nature of the ground, room height, inclination, gradient, curvature, possible obstacles, and much more. The identified footprints are mapped and recorded in a data sheet. As mentioned above, the result of the work of the indigenous ichnologists is not an inventory of all footprints but of footprints about which they can give dependable information. In this way, the indigenous ichnologists' approach differs from that of Western science, in which each individual footprint is recorded by using specific attribute systems, thus favoring description over interpretation. Ultimately, the discussions about these two approaches are comparable to the dichotomy in archaeology between two well-established methods of object analysis: the attribute analysis and the analysis of the chaîne opératoire.

The results reported below are based on data collected in a pilot study in the Fontanet, Niaux, Pech Merle, and Tuc d'Audoubert caves in 2013 (Lenssen-Erz et al. 2018; Pastoors et al. 2015, 2017). Those from the last field study in Aldène and Tuc d'Audoubert in 2018 have not yet been fully processed. Accordingly, 17 individuals were documented in Fontanet, 5 in Pech Merle, 2 in Tuc d'Audoubert, and 1 in Niaux, where these numbers are to be understood as minimum number of individuals (MNI). On the one hand, not all footprints have been examined, while on the other hand, probably not all individuals who entered the caves have left footprints. Nevertheless, the MNI produces different pictures of the composition of the groups of cave visitors. While individuals of different ages and sex can represent several families in Fontanet, in Pech Merle it is at most one family. In Niaux and Tuc d'Audoubert, only a few individuals negotiated the caves.

The investigations have shown that children with an age between 0.5 and 6 years (infans I after Martin 1928) were also in the caves and left their own traces there. Whether younger children were also present cannot be determined, because at this age children are usually carried by their mothers and therefore leave no traces of their own.

All individuals were walking barefoot in the caves. Even in Fontanet the only footprint from the Upper Paleolithic so far interpreted as a shod foot was shown by the indigenous ichnologists to having been produced with a bare foot. This is only consistent, because a single imprint deviating from the rule is difficult to explain.

In addition to the demographic data, the footprints contain further information on walking speed and the type of locomotion or the formation of the footprint. According to this, people were mainly careful when walking. The tracks of slow walking speed testify to this. Only a few individuals had it in a hurry, but there was no running at all. Slip marks testify to the short-term loss of balance, but also to the immediate recovery of control, because traces of falling have not yet been found. However, other activities were carried out as well, for which it was at least temporarily necessary to put the knee on the ground. Only in exceptional cases – as in Tuc d'Audoubert – do we know what has been done on the ground (Bégouën et al. 2009). There the coincidence of a number of extraordinary circumstances led to the recognition of a longer sequence of activities carried out by ice age cave visitors. Deep inside the cave, clay was tested, found to be good, removed, transported, and a few meters away transformed into sculptures (Fig. 2). The imprints in the clay ground show where protagonists knelt down to remove the clay and how they moved over to the place where sculptures were made – details that could only be discovered by the indigenous ichnologists.

Most of the individuals walked unspectacularly through the respective caves. Only a few tracks contain different information, for example, a person – in Pech Merle a woman between 21 and 40 years old (adultus after Martin 1928) – who carried an additional weight (Fig. 3) and in Niaux one who deliberately created the footprints by rolling slowly from the heel to the toes and, furthermore, two people who consciously walked on their heels. All individuals were physically healthy and showed no walking disabilities.

At an archaeological site, the absolute simultaneity of different activities can only be proven in special situations. This also applies to footprints which are usually difficult to associate with the archaeological finds and other findings surrounding them. For this reason, the footprints primarily document the presence and movement of people in the cave. However, in the case of the clay sculptures in Tuc d'Audoubert, a complex sequence of operations could be reconstructed from tracks.

In the course of the two field studies in 2013 and 2018, especially the last, there were no inconsistencies or contradictions in the interpretation of the approximately 1000 prehistoric human footprints examined. This expresses the professionalism and quality of the work of the indigenous ichnologists.

Currently, most of the footprints examined by indigenous ichnologists are analyzed using quantitative methods in order to verify or falsify their results in the form of a cross-test. It will be a central task to combine Western science with indigenous ichnology and to discuss the results

Tracking in Caves: Indigenous Ichnology, Fig. 2 Reading of human footprints by Kxunta, Thao, and Ciqae in Tuc d'Audoubert. (Photo Association Louis Bégouën)

Tracking in Caves: Indigenous Ichnology, Fig. 3 Female human footprint in Pech Merle. (Photo Tracking in Caves)

of both approaches. A main problem is certainly the difficulty of evaluating the results obtained by the indigenous ichnologists. But their integration into the interpretation of prehistoric footprints is still in its infancy. Following the principle of Aristotle, where the whole is more than the sum of its parts, indigenous ichnologists include the behavior of the track-maker in their interpretations from the beginning. For Western scientists, footprints are individual morphological features that are quantified as such, disconnected from the other footprints. The question of the behavior of the track-maker is handled separately and comes at the end of the statistical analyses. This methodical contrast offers great potential, and its analysis promises benefits for both sides.

For the future, these experiences mean that by applying indigenous knowledge, selected source genres of archaeology can be explored in greater depth than would be the case with conventional methods alone. While the case described here was about the knowledge of hunter-gatherers, it is to be expected that the addition of, for example, pastoral nomads in other fields of research and for other epochs will also lead to new and deeper insights.

Trackways in Archaeological Conservation and Preservation

Neville Agnew and Martha Demas
Getty Conservation Institute, Los Angeles, CA, USA

Introduction

Ichnology is the branch of paleontology that studies human and animal fossil tracks and trackways,

both of which are widespread across the world. That trackway sites are quite common is not surprising: an animal makes many tracks and traces during its life but leaves only one set of remains which, if skeletal, may be preserved in the fossil record. This entry is concerned with the preservation of trackway sites. Through the ICHNOS Project, Lockley and colleagues provide a record of some 63 hominid and human footprint sites, ordered by approximate age (Lockley et al. 2007). All of these are, needless to say, younger by far than the many known dinosaur track sites and the vastly older invertebrate trackway sites from the Paleozoic era. From a preservation point of view, it is not relevant to distinguish between categories of track maker. Hominid and dinosaur track sites in particular fascinate the public and are good exemplars pertaining to preservation and public access to exposed sites.

Definition

A number of aspects make trackways important as sources of scientific, social, and behavioral information: the size of the track maker, stride, soft tissue morphology, predatory or flight behavior, and so on. Essentially there is no substance to a track, only the imprint of tissue on the surface carries information, and it is this that is the object of preservation. Preservation thus poses challenges. Trackways are found across a spectrum of substrate types. The track surface depends on the geology of the site and varies from soil or mud to hard, weather-resistant rock in some cases of fossilized tracks. However, almost all rock types in which tracks are impressed were soft sediments, although metamorphic or secondary depositional processes after burial (e.g., limonite or calcite formation on the track surface) may alter the petrology. It is obvious that the substrate must have characteristics capable of retaining detail of the track. Thus, mud or volcanic ash fall cannot be too wet or too dry or tracks will not survive or they will be ill resolved and of little value. A further requirement for survival is protection of the tracks by rapid burial through natural processes, or through having been made in a cave as in Chauvet (Clottes 2001: 37), where erosional processes do not erase the prints. That so many traces and tracks survive in the palaeontological and archaeological record is indicative of the frequency and ubiquity of their creation; many more sites than those existing today must have been lost through erosion and clearly many are yet to be found.

Key Issues/Current Debates/Future Directions/Examples

From a preservation perspective two aspects of how trackways are valued by various constituencies are relevant. Scientific and archaeological values, falling under the disciplines of ichnology and palaeoanthropology, derive from the unique information trackways can yield that fossil bones or other archaeological evidence may not afford. Social and symbolic values emanate from public education and the way people respond to these frail traces of the past. Tracks evoke a moment in time, recent or tens of thousands or millions of years ago, and invite musings about the maker of the tracks, whether human or animal, and the circumstances under which they were formed. People thus relate powerfully to tracks, such as the iconic image of Neil Armstrong's footprint on the moon and the Laetoli hominid trails, which bracket a time span of 3.6 Ma and symbolize the journey of the human species (Figs. 1 and 2).

Essentially three options exist for the conservation and preservation of trackways. All have been undertaken at various sites. These are to lift the trackway or some of the individual prints for removal to a museum or place of safekeeping; to bury or rebury the site; to shelter it and open it to visitors; or to leave it exposed without an attempt at preservation. In each of these scenarios, high-level documentation is an essential starting point. Photogrammetry and laser scanning provide noncontact recording of surfaces in three dimensions. This is especially useful in cases where the surface is too fragile to allow molding for replication as a cast. The photographic and digital records of surfaces are a fundamental research tool and provide a standard for future condition monitoring.

Trackways in Archaeological Conservation and Preservation, Fig. 1 When Neil Armstrong trod on the surface of the moon, July 20, 1969, images of his footprints were instantly recognizable as symbolic of humankind's first tentative steps into the cosmos. (Photo courtesy of NASA)

Trackways in Archaeological Conservation and Preservation, Fig. 2 At the site of Laetoli, trails of three hominids, two walking in tandem, and crossed by hipparion tracks (*bottom* of image), were imprinted 3.6 Ma ago. The southern part of the trackway is shown after re-excavation and conservation in 1995. (Photo: 1995, J. Paul Getty Trust)

The decision-making process as to whether the site is to be lifted, buried, sheltered, or left exposed can be contentious when different stakeholders or constituencies are involved if, for example, either the scientific or social values, including economic ones, take the foreground to the detriment of the others. Significance issues that need to be weighed in the decision include the environment and landscape in which the trackway exists. To move a site in toto, or to remove only individual prints which destroy the relationship between them (gait, stride length), is contrary to the accepted ethic of conservation in context. Both are irreversible interventions. Removal ascribes scientific value only and overlooks the cultural and natural significance in the landscape. On the other hand, leaving a trackway in situ requires protection. If exposed, inevitably weather and erosion will destroy the site. Consequently, for many preservationists, the options then become sheltering (Stanley-Price and Matero 2001) or reburial (Nixon 2001; Stanley-Price and Burch 2004). The excavator, scientific community, and the public often regard reburial as the less desirable option: it removes the evidence from access and view. If the trackway site is of high significance, there is a tendency for a decision to be taken for the site to be opened for visitation, usually under a structure that serves a protective and interpretive function. This is a time of great risk for an excavated site since temporary protection and security may not be adequate while design and funding for a shelter are being sought. As a number of case studies reveal, none of these options is ideal, and each has advantages and disadvantages. Examples are considered below.

Lifting a Trackway Site: Glen Rose Dinosaur Trackways

The dinosaur footprints in the lower Cretaceous deposits of the Paluxy River near Glen Rose in Texas serve to illustrate problems that may arise when a trackway site is relocated. The site has been known since 1908 and comprises exceptionally well-preserved carnosaur and sauropod footprints in immediate proximity to each other. A large section of the dolomitic trackway was removed in 1939 and taken to the American Museum of Natural History (AMNH), and a further part went to the Texas Memorial Museum (TMM) where it is housed in a special building. The section in the TMM has displayed severe deterioration, including surface spalling and exfoliation associated with the crystal growth of soluble salts, principally epsomite. The environmental conditions in the building, including excessive humidity and capillary rise from ground water, are reportedly responsible for the condition of the trackways (Shelton et al. 1993).

It is apparent that the inadequate monitoring of the condition of the tracks in the TMM permitted deterioration to occur to an advanced stage before the damage was fully realized. The other part of the contiguous trackway in the AMNH apparently has not suffered damage. The remaining trackways, still in situ, have also shown no deterioration and are protected by the Texas Parks and Wildlife Department in what is now Dinosaur Valley National Monument (Farlow 1993).

A related example is from South Africa: The human footprint site is situated about 130 km north of Cape Town on the Langebaan Lagoon. Here a few tracks were found in dune rock dating to 120,000 years BP. Because the site is frequented by visitors who habitually carve graffiti into the soft dune rock and also because of vulnerability to wave erosion, the tracks were removed by helicopter and transported to the Iziko Museum in Cape Town (Roberts 2008). The fragmentary front print was lost during this rescue, though a cast exists.

Reburial: Laetoli Hominid Trackway Site

The earliest hominid trackway, 3.6 Ma old, is at the site of Laetoli in Tanzania (Fig. 2). The Laetoli tracks exemplify many of the issues and controversies that bear upon highly significant sites and their preservation. When, in 1978, fossil footprints of a purported human ancestor (*Australopithecus afarensis)* were discovered during a palaeontological expedition led by Mary Leakey, scientific and public attention was immense, reflecting both their scientific and symbolic significance. The prints, partly exposed through erosion, were found at the site of Laetoli, to the south of Olduvai Gorge, where Louis and Mary Leakey did their pioneering work researching human evolution. Securely dated, the footprints resolved one of the major debates in palaeoanthropology. At Olduvai and other sites in Africa and beyond, the search for evidence of human evolution has focused on fossil bones; but while fossils have been the primary means of understanding our origins, they cannot answer all the scientific questions. One debate had been the development of the brain in relation to bipedalism. The Laetoli trackway was evidence that bipedalism preceded development of the brain. Excavated in 1978 and 1979, the trackway consists of footprints of three individuals in two parallel trails some 30 m long, preserved in volcanic ash. The Leakey team used various techniques to document the trackway, including molding, casting, and photogrammetry, before reburying the trails in 1979 as a means of protection. After reburial the site revegetated. Although its condition was not known, nor was it monitored because of its remoteness, there was concern that root growth from Acacia trees was damaging the tracks. A multiyear conservation project involved re-excavation, removal of trees and roots, stabilization of the trackway and site, scientific restudy, and reburial (Fig. 3) (Demas and Agnew 2006). A small-scale replica reburial trench was created adjacent to the site to provide surrogate monitoring through periodic re-excavation (Agnew and Demas 2004). Reburial removed the trackway from future public access. As a means of compensation, a cast of the trackways and interpretive material was created at the nearby Olduvai Museum. More than 10 years later, a political decision was taken, but yet to be implemented, to reexpose the tracks for tourism.

Another example is from the Willandra Lakes Region World Heritage area. The Willandra Lakes

Trackways in Archaeological Conservation and Preservation, Fig. 3 Southern part of the Laetoli trackway during reburial in 1995 showing the reburial stratigraphy incorporating sieved local sands and geosynthetic materials with a final boulder capping. (Photo: 1995, J. Paul Getty Trust)

area was the site of discovery in 2003 of human footprints dated to 20,000 years BP (Webb et al. 2006). The site has revealed over 700 prints and 23 trackways of men, women, and children. Apart from the tracks themselves, the Willandra Lakes World Heritage area is also important for an understanding of Australia's prehistory through the skeletal collections (http://www.visitmungo.com.au/world-heritage). Three traditional tribal groups maintain responsibility for the site with the assistance of the New South Wales National Park Service and other organizations. After documentation and scientific study, the footprints were buried under sand and a covering of a synthetic textile as protection from wind scour and to provide insulation against damaging freeze-thaw (Fig. 4). Considerable discussion took place among the traditional communities and professionals regarding the future of the site: whether it should be replicated for display, on site or nearby, or buried permanently, or opened to visitation under a shelter. Based on clear photographic evidence of rapid deterioration of exposed tracks, the decision was made to keep the site buried. Interpretation of the tracks is done off-site.

Sheltering: Lark Quarry Dinosaur Stampede

Known today as the Dinosaur Stampede National Monument, in central Queensland, Australia, the site was one of the first three places to be listed on the National Heritage List in July 2004. Located 100 km south of the town of Winton, the site features unique evidence of a dinosaur stampede, with almost 4000 tracks clearly visible in an area of some 210 m^2 (Fig. 5). The footprints are interpreted as a fossilized record of a predator stalking and causing the chaotic stampede of around 150 bipedal dinosaurs, varying in size from that of a chicken to larger types about the size of Australia's flightless bird the emu.

The site is claimed to be the only known dinosaur stampede and a record of a few minutes in time during the Cretaceous era, 95 Ma ago. Today an ecologically sustainable building covers the trackways protecting the footprints from weather, humans, and wildlife. The state-of-the-art building is, however, not the first shelter to be built over the site. Excavated in 1977–1978, the significance of the site resulted in a decision, despite its remoteness and lack of infrastructure and personnel, to open it to the public. A number of organizations were appointed as joint trustees of the site, and while funding was being secured for a roof, the site was protected with straw under plastic sheeting. The problems that subsequently arose, during and after construction of the flat pentagonal roof, are numerous. They range from burning of the straw and loss of a holotype footprint during unsupervised construction of the roof, to the occupation by kangaroos seeking shade, to souveniring by visitors since the site was not staffed for security or interpretation. Additional problems were flooding of the site from the uphill slope, dust accumulation in the prints, and a general inability of the trackway to be understood by visitors (Agnew et al. 1989).

Nor was the new building (Fig. 6), erected in 2001, without problems. Collapse of a large

Trackways in Archaeological Conservation and Preservation, Fig. 4 In the flat barren landscape of the Willandra Lakes, the 20,000-year-old human prints are shallowly buried by layers of permeable synthetic textile to protect them from freeze-thaw cycles and wind scour. Trackways in Archaeological Conservation and Preservation, Fig. 5 Some of the 4000 individual tracks of dinosaurs dating to 95 Ma ago at the Lark Quarry site. Image shows ornithopod and coelurosaur and two of the eleven carnosaur tracks. (Photo: 2007, J. Paul Getty Trust)

rammed earth internal wall, intended to provide thermal stability of the interior environment, onto the visitors' walkway and trackway, occurred not long after the site had been opened to the public (Meiklejohn 2003).

Unprotected Sites: Formby Point

Trackways may be too extensive for practicable preservation measures to be warranted. Nor would the high cost justify attempts to save them from erosion. Under such circumstances, full documentation and recording is the only option. There are many such sites. Well known are the intertidal coastal trackway sites on the west coast of Britain. The Formby site, dated about 5500 BP, is of high scientific value and the prints of children, women, men, and a number of animals, including deer, aurochs, and birds, have been recorded. About 145 different trails at Formby alone have been noted, and as the succession of silts and sands become exposed during accelerated beach erosion, the imprint bearing sediments are revealed. Photography of the footprints, recording their positions, and lifting and making casts of selected

Trackways in Archaeological Conservation and Preservation, Fig. 6 The second protective structure built in 2001 over the Lark Quarry dinosaur stampede trackway. (Photo: 2007, J. Paul Getty Trust)

specimens has been an ongoing research project (Roberts et al. 1996).

Discussion

All exposed remains are subject to the vicissitudes of weather and damage, none more than tracks, which are essentially ephemeral traces comprised only of the substrate itself. Stabilizing fragile tracks may require treatments, such as surface consolidation, reversible crack filling, and edge buttressing of the Lark Quarry trackway (Agnew et al. 1989), but should be undertaken with due caution; strengthening of the substrate for purposes of molding is of particular concern, as the experience with the application of Bedacryl on the Laetoli tracks in 1978 demonstrated (Demas et al. 1996). The use of 3-D technologies to capture virtual reconstructions and create physical replicas now offers a noninvasive alternative to molding. Precise, accurate, and accessible archived documentation and periodic monitoring are the most important measures that can be taken for the preservation of these fragile and unique traces regardless of other interventions undertaken.

When the significance of a site is high, the desire to open it to visitation may override sustainable considerations of preservation. Seldom are all the threats or limitations taken fully into account. These may include, to name a few, damage to the site while fundraising and preparations are being made for sheltering and interpretation; lack of security and long-term maintenance of a protective structure; insufficient staffing and infrastructure; and unanticipated consequences of sheltering such as dust accumulation obscuring the tracks, birds and animals in the shelter, accumulation of damaging soluble salts, plant growth, and so on. It is unusual too for an objective assessment of the visitation potential to guide the decision. Thus, when visitor numbers do not meet expectations, there may be a decline in funding and inevitable neglect over the long term.

Trackways of significance will continue to be discovered. Their preservation requires a complex decision-making process based on thorough understanding of significance, investigation of environmental conditions, careful assessment of threats, and long-term human and financial resources.

Trade and Exchange in Precontact East Polynesia

Jennifer G. Kahn
Anthropology Department, College of William and Mary, Williamsburg, VA, USA

State of Knowledge and Current Debates

The vast Eastern Polynesian triangle where 40 island communities live is delineated by the Hawaiian Islands, Easter Island (Rapa Nui), and New Zealand (Fig. 1). Eastern Polynesia includes the central archipelagoes of the Society, Cooks, Australs, Marquesas, Tuamotu, and Mangareva Islands which are collectively known as Central East Polynesia (CEP), with the more remote islands of Hawaii, Rapa Nui, and New Zealand found at the margins. Eastern Polynesian islands are more isolated than those found in the Western Pacific. As an example, the remote Hawaiian Islands are separated by c. 4000 km from their nearest neighbors, the Tuamotu Islands.

Background

Questions of how the islands in Eastern Polynesia were first colonized, whether by drift voyaging or intentional navigation, have long been debated by scholars ever since the time of Captain Cook's first voyages to the region. From an ethnographic perspective, Eastern Polynesia differs from Western Polynesia in terms of religion, material culture, and kinship (Burrows 1938). Kirch and Green's phylogenetic approach (2001), combining linguistic, genetic, archaeological, and ethnographic data, illustrates that Eastern Polynesian cultures share many cultural innovations and language traits, arguing for the presence of an Eastern Polynesian homeland prior to the settlement of the remote margins of Eastern Polynesia. Experimental voyaging, computer simulation models, and newly refined Eastern Polynesia chronologies argue for a rapid settlement of CEP and the Hawaiian archipelago c. AD 900–1100, with

Trade and Exchange in Precontact East Polynesia, Fig. 1 Map of the Polynesian triangle

New Zealand being the last island settled in the thirteenth century (Kahn in press; Kirch 2017a). This supports Eastern Polynesian oral histories and early European explorer accounts which document expert navigators and periods of widespread long-distance voyaging in the precontact period (Di Piazza and Pearthree 2007; Finney 1997).

Chronology and Scale of Long-Distance Voyaging, Trade, and Exchange

While it is now recognized that the remote archipelagoes of Eastern Polynesia were intentionally settled using sophisticated watercraft and navigational techniques, to what extent did long-distance voyaging continue after first island settlement in Eastern Polynesia? What long-term benefits might trade have offered isolated island communities and to what extent did such communication spur regional patterns of social change? And to what extent did exchange at the intra-archipelago level, namely, between islands within the same archipelago, perhaps spur or support the development of status differentiation? These are questions continually debated by archaeologists in the region and touch upon larger global archaeology themes, including the role of trade and communication in establishing and maintaining socioeconomic relations, their role as a colonizing strategy, and their role in the development of cultural change (Weisler and Walter 2017).

Archaeologists in Polynesia have focused on documenting the trade of durable material culture. Numerous studies have demonstrated the movement of adzes, stone tools fashioned from fine-grained basalt, basalt oven stones, and pearl shell, a large bivalve prized as a material for fabricating fishhooks and body ornaments. These highly prized materials had restricted spatial distributions, lending themselves readily to transport and trade. Analyses of adzes have most commonly been used, including X-ray fluorescence (EDXRF, WDXRF), inductively coupled plasma-atomic emission spectrometry (ICP-AES), and radiogenic isotope analyses to geochemically characterize artifacts and link them back to their geological source of origin. Yet archaeologically we can only track the movement of highly durable goods, which was likely only a small portion of the total amount of goods traded (Kirch and Green 2001).

Ethnohistoric and archaeological data suggest that a wide range of durable and nondurable

goods were traded in Eastern Polynesia. In addition to marriage partners, traded items included long white dog hair and bird feathers used in elite regalia; animals such as turtles, pig, dog, and chicken; plants such as coconut, taro, and candlenut; plaited vegetal mats; bark cloth for clothing; shell tools; basalt adzes and poi pounders (the latter were for preparing foodstuffs and medicines); and obsidian (Weisler 1997; Weisler and Walter 2017). Many of these goods had limited spatial distribution or were more readily produced on younger high islands rich in resources versus older atolls with more marginal environments lacking highly productive soil, easy access to water, and raw materials such as basalt. Thus, to some extent post-colonization trade was likely key for balancing out resource differences among the different island types (and island ages) found in the Eastern Polynesian region. It was also likely instrumental to the sustainability of island communities in resource-poor contexts, where daughter communities had to rely heavily on ties to motherland communities, particularly after profound climatic events such as cyclones and droughts.

But what about other social benefits of trade vis-à-vis group identity and status differentiation within chiefdoms? Ethnographic data widens our understanding of the meaning of exchange, prompting archaeologists to look beyond purely functionalist interpretations. Modern ethnographies of Austronesian societies, whose cultures speak languages in the same language family as those found in Polynesia, support the notion that gift exchange plays critical sociopolitical roles in regional and community contexts. The frequency of local domestic exchange and gift giving, including the quantity and quality of the goods presented, confers certain kin groups distinct advantages over others (McKinnon 2000:170–171; Parmentier 1987:114). Weiner (1992) emphasizes that the possession and exchange of inalienable objects or heirlooms, such as mats and adzes, both establish and maintain group identity. Gift exchange offers kin groups, and particularly high-status kin groups, an avenue to create and establish social difference and to widen their alliance networks. This, in turn, maintains and perpetuates the status of the involved kin groups through time. This implies that comparative archaeological investigation of gift exchange activities has relevance to understanding social relations at the local, community, and regional scales, both within and between archipelagoes.

As archaeological models and ethnographic models attest, the frequency, extent, and scale of trade among and between archipelagoes, as well as their change through time, are important elements to understanding regional diversity in Eastern Polynesia. Below I provide case studies documenting (1) early East Polynesian inter-archipelago long-distance exchange and its diminution through time, (2) the role of intra-archipelago exchange in supporting elite identities and hierarchies, and (3) trans-regional contacts between Eastern Polynesia and South America. The first two case studies provide examples of organized and sustained exchange systems that lasted for several centuries, while the last case study is rather unique in documenting a short period of contact with sporadic exchange.

Early Eastern Polynesian Inter-archipelago Exchange and Its Diminution Through Time

In examining the role of inter-archipelago exchange, I will first turn to the Eiao adze quarry, situated at the northwest end of the Marquesas Islands (Fig. 2). The island is currently uninhabited and, given its lack of natural water resources, was likely not permanently inhabited in the precontact period. Yet the island is home to abundant sources of fine-grained, tool-quality basalts and has copious evidence for in situ tool manufacture (Charleux et al. 2014; Rolett et al. 1997).

Early XRF studies in Eastern Polynesia documented the impressively long reach of the Eiao quarry, with adzes transported and exchanged into the Society Islands (Weisler 1998) and the northern Marquesan group (Rolett 1998; Rolett et al. 1997). Subsequent studies have provided abundant evidence for the movement of Eiao adze material into CEP and throughout the Marquesan archipelago (Fig. 2; see Allen 2014; McAlister and Allen 2017). These include imports into the Tuamotu Islands (Collerson and Weisler 2007), the Line Islands (Di Piazza and Pearthree 2001), the Cook Islands (McAlister et al. 2013; Weisler

Trade and Exchange in Precontact East Polynesia, Fig. 2 The Eiao Adze quarry and networks of long-distance exchange

et al. 2016), and the Austral Islands (Hermann 2013, 2016; Hermann et al. 2017). The distribution of Eiao adze material provides direct evidence for precontact long-distance exchange and interaction between CEP archipelagoes. The most remote corners of East Polynesia, including Easter Island, New Zealand, and the Hawaiian Islands, have limited evidence for long-distance exchange and do not appear to have played a central role in the CEP interaction sphere. Materials evidence for items moving in or out of remote East Polynesia are restricted to a Tuamotuan adze sourced to the Hawaiian Islands (Collerson and Weisler 2007) and a New Zealand shell chisel made from an exotic shell (Davidson et al. 2011).

Archaeologists have attempted to model the scale and timing of long-distance trade and interaction in CEP using dated contexts where Eiao adze material has been found. While sample sizes of Eiao imported material are still low, there is a broad consensus that CEP long-distance trade and exchange was most frequent in the centuries just after island colonization. As several researchers have noted, Eiao material and other imported adze material are most prevalent in early settlement period sites, with frequency rates falling off c. AD 1400 (Rolett 2002; Weisler 2002). However, in some areas such as the Cook Islands, long-distance interaction seems to have continued up until the late AD 1500s (Weisler et al. 2016).

Following this, archaeologists have argued that CEP long-distance voyaging seems to have been an important colonization strategy, linking archipelagoes with varying resource bases as well as parent and daughter communities (Weisler 2002). Over time as human populations increased, local aggression and chiefly competition rose and local resources were diminished. It is likely that the somewhat risky and expensive patterns of long-distance voyaging in CEP were replaced with greater economic inputs into local economies (Rolett 2002). Once the larger central nodes of the CEP exchange network, such as the Society Islands, diminished their role in long-distance exchange, this likely had widespread effects on the entire CEP interaction sphere. This cessation adversely effected the more remote and resource-poor communities involved in the CEP interaction sphere, such as Pitcairn and Henderson Islands, whose connections to the mother community of Mangareva were necessary for survival (Weisler and Walter 2016). Ultimately Henderson and the Pitcairn Islands were abandoned, becoming "mystery islands" with precontact evidence of Polynesian settlement but lacking habitation at the time of European contact.

The timing of the cessation of long-distance voyaging in particular archipelagoes in CEP remains unresolved, while broad patterns suggest contraction of regional networks c. AD 1400. Weisler et al. (2016) have argued that the cessation of long-distance trade likely differed among CEP archipelagoes and was dependent on island geography (age, type, size, accessibility, resources), dates of colonization, growth of human populations, and local evolution of social conditions, including human-environment interactions and ecosystem sustainability.

Intra-archipelago Exchange in Eastern Polynesia: Elite Identities and Hierarchies

In examining the role of intra-archipelago exchange, I will first turn to the Society Island case study. The Society Islands are the largest high-island archipelago in CEP. Like all hotspot formations, the Society archipelago has a clear age/resource gradient, with the older, drier islands found in the Leeward group and the younger, wetter islands in the Windward group (Fig. 3). The Leeward and Windward groups are separated by a 2–3-day sail by traditional outrigger canoe. The Leeward group and Windward group each formed a unified chiefdom in the period just prior to European contact, following an earlier period whereby several independent chiefdoms on separate islands were unified via coercive consolidation. During the Classic Period (AD 1650–1767), each group saw the development of regional styles of temple architecture and forms of material culture (Kahn in press; Kahn and Kirch 2014). The Society Islands are the only CEP culture to develop into a complex chiefdom with three-plus social classes (elite paramount chiefs, secondary chiefs, administrators, commoners), highly formalized status differences, large centralized polities, and high overall population (c. 120,000).

Ethnohistoric sources document that there was considerable exchange and movement of goods and ideas between the Windward and Leeward groups. The Leeward group produced coconut oil and plank boats for exchange, while the Windward group traded surplus bark cloth and starchy foodstuffs (Fig. 3). While incomplete, the sources record how Maupiti exported adzes and stone food pounders (*poi* pounders), while Tahiti also exchanged adzes. Intermarriages of chiefly lines were found between all islands within the archipelago, but were pronounced between Mooréa and Tahiti and between Tahiti and the Leeward group. The movement of *marae* (temple) stones, particularly cornerstones (*ofa'i faoa*) from Leeward group *marae*, and using these as "founder stones" for Windward group *marae* was a material manifestation of intermarriages that legitimated chiefly rank and elite alliances (Henry 1928; Kahn and Kirch 2014).

Given the Society Island ethnohistoric accounts, many exchange items may have circulated in part during gift exchange ceremonies commemorating the joining of chiefly lineages in marriage. There has been only one detailed analysis of the circulation and movement of Society Island adzes in the development/expansion and Classic Periods. Data from Mo'orea Island indicate intra-archipelago trade in adzes began as

Trade and Exchange in Precontact East Polynesia, Fig. 3 Intra-archipelago exchange between the Windward and Leeward Society Islands

early as AD 1350 and continued up until European contact (Kahn et al. 2013). These 'Opunohu Valley stone tool artifact assemblages lacked evidence for inter-archipelago exchange, with no imports coming in from major Western Polynesia adze quarries or major CEP quarries such as Eiao. Yet they had high frequencies of off-island imports coming from within the archipelago (30%), with c. 26% likely coming from Tahiti and c. 4% likely coming from Ra'iātea. Elite and commoner residences did not differ in their distributions of local and exotic (off-island source) stone tools. However, 67% of these imports were recovered in ritual sites with ceremonial function (*marae*, shrines) or sites with specialized function (feasting, craft production, community use, priests' use). This suggests that socio-ritual elites, including chiefs and craft specialists (*tahua*), practiced local prestige-good gift exchange, some of which included adzes. Such interactions would have solidified sociopolitical and ideological alliances between Windward and Leeward group elites, in effect both creating and maintaining formalized social hierarchies.

These data suggest that Polynesian adzes had more than a strictly utilitarian function, a theme that is hinted at in the ethnohistoric records of many island groups. Adzes were often used in the production of ritually charged material items including canoes and god figures as well as houses and offering platforms found in and around temples (Firth 1967a; Lass 1998; Malo 1951). In the Society Islands, specialist canoe builders used adzes in a highly ritualized manner. Chants record how specialists placed their adzes "to sleep" in the

walls of the temple at the end of the day while asking the god Tane to consecrate the tool for the next day's work.

> Go and take hold of the axe, In the aperture in Havai'i, Hold, that it be taken out enchanted, Made light; that it may produce sparks in doing varied work. It is whetted with fine sand, Made smooth with loose-grained sand; It is set in a firm handle of sacred *miro*, United with many-stranded sennit of Tane. The axe will become sacred in the brilliant sennit of the artisan *(tahu 'a),* Which touches and holds as a girdle for the axe, For the handle of the axe, The back of the axe, To make one the axe and the handle, To make light the axe, To consecrate the axe, To impel the axe, To complete the axe, To give power to the axe. (Henry 1928: 146–147)

Other traditional chants (Henry 1928: 406–407, 414) and the Tahitian lexicon (Davies 1851: 37) document the practice of naming and curating "ancestral" adzes (for an example of this practice elsewhere in Oceania, see Firth (1959)). Gift exchange of valued adzes "from afar" and their ongoing use in ritualized production activities likely formed one element of much larger alliance-building strategies exploited by Society Island elites. Similar correlations between nonlocal stone tools and elite ceremonial sites are expressed in some later period. Hawaiian case studies (Kirch et al. 2012) demonstrating the importance of intra-archipelago and intradistrict adze exchange in the elite wealth economies of Polynesian chiefdoms and Archaic states (Hermann 2015). While some Eastern Polynesian stone tool assemblages late in the chronological sequence likewise show continued intra-archipelago exchange (Allen and Johnson 1997; Rolett 1998), others, including some Austral Island and Cook Island assemblages, have a majority of locally produced stone tools (Hermann 2013; Weisler et al. 2016). While sample sizes remain small, current data suggest that patterns of intra-archipelago exchange late in the sequence may differ among different Eastern Polynesian archipelagoes.

Transpacific Contacts Between Eastern Polynesia and South America

Sweet potato ultimately originated and was domesticated in South America (Austin 1988; Yen 1974), but it has long been an important staple food item in Polynesia, indicating that it was a transpacific introduction. How exactly was sweet potato first brought to Polynesia, when did this occur (i.e., was it brought by the first Polynesian colonists, or was it a secondary introduction, either by Polynesians or by European explorers?), and why was it introduced? Current genetic and linguistic data indicate that this tuber was introduced during the prehistoric (pre-European contact) era into Polynesia through the dispersal of human agents (Ballard et al. 2005). Genetic analysis of sweet potato herbarium samples collected by early European explorers supports that the cultivar represents a precontact diffusion from South America (Peru-Ecuador area) into Polynesia (Roullier et al. 2013). Ethnohistoric and linguistic evidence suggests that the Polynesian word for sweet potato, *kumara*, comes from Quechua speakers of northwestern South America who were intensive sweet potato cultivators (Fig. 4, Scaglion 2005).

When it was first realized that sweet potato originated in South America and was introduced into Polynesia, one argument was that sweet potato was a precontact (pre-European contact) introduction into Polynesia. Other evidence suggested that sweet potato may have been a later introduction, perhaps brought by European explorers. In the last 30 years, fragments of carbonized sweet potato have been found in several Eastern Polynesian archaeological sites. These include well-dated prehistoric contexts in Mangaia (Cook Islands), Easter Island, and the Hawaiian archipelago (Hather and Kirch 1991; Kirch 2017b; Ladefoged et al. 2005; O'Brien 2000). Archaeologists now accept that sweet potato was imported into central Eastern Polynesia by c. AD 1000–1100, and it is most likely that it spread into the margins of Eastern Polynesia several centuries thereafter. Sweet potato is then a secondary introduction, brought to Eastern Polynesia a century or two after the region had first been colonized, but many centuries before European contact. These data support the tripartite hypothesis, articulated by Yen (1974) and Green (2005) and further developed by Clarke (2009), where the first event was the prehistoric dispersal of sweet potato to Eastern Polynesia, followed by later historic events with the dispersal of sweet potato into the Western Pacific by European explorers.

Trade and Exchange in Precontact East Polynesia, Fig. 4 The Eastern Polynesian triangle and South America: word glosses and archaeological evidence for precontact sweet potato. modified from Roullier et al. 2013

The question remains: did natives from South America bring sweet potato to Polynesia, or did Polynesians make contact with South America and return with the sweet potato? Most agree that it was Polynesians who made a two-way voyage and were responsible for the initial transfer of sweet potato, rather than South American voyagers, given the extensive evidence for long-distance voyaging capabilities for Polynesians (Fitzpatrick and Callaghan 2009). After this initial transfer to Eastern Polynesia, this food item spread westward into Central Polynesia, both by Polynesian and later European traders. The prehistoric circulation of sweet potato within Eastern Polynesia and to the west broadly supports that Eastern Polynesians were carrying out long-distance voyaging up until c. AD 1400. Other direct data for transpacific contacts are limited and include the possible transfer of bottle gourd from South America into Polynesia (Clarke 2009). Based on chronological data and genetic data, Storey et al. (2007) have argued that chicken bone from the El Arenal site in south-central Chile is evidence for Polynesian introduction of chickens into South America, but this continues to be debated (Gongora et al. 2008; Storey et al. 2007, 2012; see Horsburgh and McCoy 2017). Genetic analysis of human skeletons has proved inconclusive (Fehren-Schmitz et al. 2017; Gonçalves et al. 2013; Moreno-Mayar et al. 2014).

But why was sweet potato adopted when Polynesians already had a series of good crops? It is quite similar in appearance to yam, which already was a Polynesian cultivar when sweet potato was introduced. However, unlike yam, sweet potato can be planted year round; thus it was easily adopted by Polynesians who already had experience with a similar food crop. Perhaps a canoe load of East Polynesians were taken off course by a large storm and landed in South America. Once there, they would have sought out foodstuffs like sweet potato which were similar to plants they had already cultivated. They then brought sweet potato back to East Polynesia with them on their successful return voyage (likely as a foodstuff to eat on the voyage). Once they returned, they had leftover sweet potato which they continued to cultivate and trade because the plant had a high yield and was well adapted to Polynesian styles of cultivation.

Trade and Transport in the Ancient Mediterranean

Sitta von Reden
University of Freiburg, Freiburg, Germany

Introduction

The subject of trade and transport leads into different questions and forms of analysis depending on the perspective adopted. From an economic point of view, trade is part of developing systems of exchange by which the production and consumption of goods are linked over small and longer distances. Major questions include which and what quantities of goods were traded where and by what means, how much of a surplus was available for trade, and how effectively trade, transport, and currency fulfilled their purposes within a specified geographical range. Which social, political, and technological circumstances affected volumes of trade, and what factors stimulated or prohibited the development and expansion of markets? The emergence of price-setting markets is central for economic history. Economic historians are aware that trade via markets is only one possible way of moving goods and services from their place of production to that of consumption, but it is the one with the greatest net profit and thus the condition for growth. Anthropologists do not look for the evolution of markets. From this perspective, exchange is an index for different types of social and political organization. Trade via price-setting markets controlled by supply and demand is only one type of exchange mechanism that developed under particular social and political circumstances in early modern Europe. In other social and political settings, distribution controlled by states (such as tribute and redistribution), or by social networks (in which gift exchange and other morally controlled reciprocal exchanges are practiced), is more suitable for linking production, consumption, and people. Trade itself can take different forms of organization, shading into barter, redistribution, or gift exchange, depending on the type of social organization in which it develops. For archaeologists, finally, trade is above all a sign of cultural exchange, interaction, and contact. Traded artifacts, their style, and material composition signify the combined flow of resources, ideas, and information between groups of distinct identities and resource endowments. Archaeologists investigate the directions and scope of such flows in order to identify the geographical range of cultural influence and development. Economic questions, especially links of production and consumption, are analyzed too, but the nature of archaeological evidence points to quantitative and technological rather than to institutional and social characteristics of trade. In the last quarter of the twentieth century, economic, anthropological, and archaeological perspectives have been fruitfully combined in order to investigate ancient trade not just as a simpler version of later European trade but as a subset of competing and interdependent forms of exchange which characterize and reflect different types of social organization, cultural interaction, and economic development at different periods of time (Bang 2008; Wilson et al. 2012).

Definition

Trade can be defined in different ways. It may refer to the peaceful buying and selling of goods

in contrast to moneyless barter, gift exchange, piracy, and violent forms of appropriation; it may refer to transactions external to a society rather than to their internal ones; it may refer to an exchange of resources where the material value of the goods exchanged is more central than the celebration of the relationship in which the valuables are exchanged; or it may be defined as a commercial exchange in the hands of a clearly defined social group guided principally by profit rather than other motives. Each of these definitions has been contested in recent years, but they are equally valid as long as they are not regarded as the very essence of trade across cultures and time. For classical antiquity, it is most suitable to define trade as the external exchange of material goods (which included slaves and animals) distinct from either barter or gift exchange. It can then be asked how trade, and the social groups undertaking it, interacted and how trade overlapped with barter, gift exchange, piracy, plunder, and their respective representatives. It is not helpful, however, to define ancient trade by the involvement of money, markets, professional traders, or the profit motive. Although all of the aforementioned factors played some, and at times important, roles in ancient trade, their absence did not mean an absence of trade.

The terms closest to the proposed definition of trade are in Greek *emporiē* (seaborne commerce) and in Latin *negotiatio* or *commercium* (commerce). In the early writings of Hesiod and Homer (eighth/seventh century BCE), we also find the term *prēxis* which referred to the kind of trade Greek aristocrats practiced in contrast to the trade pursued by lesser people and foreigners (Tandy 1997: 75). Yet the distinction is no longer found in the sixth century BCE, confirming that it was a social and cultural polemic emerging from social threats associated with anonymous trading contacts.

Key Issues and Current Debates

Sea transport was the cheapest way of carrying goods over distance. From c. 1400 BCE, deep-hulled ships are attested from the Near East and Egypt, which were propelled by a sail, rather than oars, to allow space for the cargo. Ships could vary in size considerably. Some were fairly small (e.g., less than 14 m), carrying loads of 20 t or less. By the Hellenistic period, ships of a carrying capacity of c. 150 t were quite normal, and those of 350–500 t not rare (Parker 1992). Transport by land was long regarded by scholars as too expensive in comparison to seaborne trade. For a bulky commodity like grain, a sea voyage added c. 2% per 100 miles to the costs, whereas freight charges over land by mule or cart could add over 50% (Morley 2007b: 26). But costs of transport varied considerably according to both commodity and region. From the fourth century BCE onward, the road system in Italy facilitated the transport of goods over land, while extensive finds of wine amphorae on sites in Gaul and southern Germany from the early second century show that land transport did not prohibit exchange networks from developing where demand emerged (Patterson 1998). It should be noted, however, that the Greeks in the Hellenistic period were quick to establish their own sea routes to India and Arabia via the Red Sea and the Arabian Gulf to reduce the amount of distance to be covered by over land caravan routes (Sidebotham 2011).

The vitality of Greco-Roman trade emerged within a particular ecosystem and successful human attempts to overcome ecological constraints. The Mediterranean is an ecological zone with similar climate, fauna, and flora that support similar strategies of production, consumption, and risk management. At the same time, the zone has a great diversity of landscapes, microclimates, and resource endowments, which fosters agricultural specialization and diversification. There is, for example, a great diversity of annual rainfall, which means that droughts and crop failure in one region may not affect another nearby. Raw materials, such as metals, stone, wood, or clay, are not evenly distributed, while the soil produces very different qualities and quantities of staple foods (grain, vine, and olives). The indented Mediterranean coastline, moreover, encourages small-scale autarkic settlement, while the sea with its many islands supports communication and exchange. Large numbers of rivers open up into the sea, connecting dispersed hinterlands with Mediterranean Sea routes and, conversely,

facilitate transport of goods from continental sites. The possibilities of transgressing a local ecosystem successfully are thus comparatively easy and at the same time rewarding. "Connectivity" is the term that has been coined for this typical Mediterranean pattern of settlement and communication, providing a helpful concept for understanding the political and ecological conditions of Mediterranean trade during classical antiquity (Horden and Purcell 2000).

Mycenaean Linear B tablets of the Bronze Age are virtually silent about trade, although self-definition through exotic materials is characteristic of the Mycenaean elite from the Shaft Grave period onward (Bennet 2007: 201). Trade and exchange concentrated, rather, in the Eastern Mediterranean between Egypt, the Levantine coast, and its hinterland (Broodbank 2013). Crete also plaid some part in it. Four documents from the Knossos Ld (i) series mention *xenwia* (cloth), which probably referred to cloth "for export." Three Bronze Age shipwrecks, two found off the southern coast of Turkey and one at Point Iria in the southern Argolid, provide archaeological evidence for the substantial movement of goods in the Aegean during that period. The largest of the three, which was perhaps 16–17 m long, carried 10 t of copper, a ton of tin, 175 blue glass ingots, 150 Canaanite jars, and 10 large Cypriot containers containing over 100 pieces of Cypriot fine-ware pottery. Lead isotope analysis of the copper ingots in combination with the Cypriot pottery suggests that the ship was on its voyage from Cyprus into the Aegean, after having stopped for ivory in Syria and possibly Egypt. High-value objects (glass, copper, and tin) indicate that it moved goods at the highest level of social interaction (ibid.). Contemporary literary evidence from el-Amarna in Egypt suggests, moreover, that such valuables were presented as gifts or tribute to maintain diplomatic ties between royal houses (Aubet 2001: 134–135), although the involvement of professional middlemen or agents in such exchanges is not unlikely.

Archaeological and literary evidence for the movement of goods and people across the expanse of the Mediterranean basin increases in the late ninth and early eighth centuries BCE after a period of rather more localized interaction during the Early Iron Age. Greek settlements participating in this movement were above all Corinth, Chalkis, Eretria, Miletus, and Phokaia. Yet undoubtedly pioneering were the Phoenician cities of the Levant, above all Tyre. By the end of the ninth century, Phoenicians had founded trading colonies in Cyprus (c. 820 BCE), Spain (early eighth century), North Africa, Sicily, and Sardinia. The Greeks followed with their earliest colonial foundation at Pithecusae/Ischia in c. 750 BCE and some kind of regular presence at Al Mina at the mouth of the river Orontes in Syria. Both of the so-called Lyre-Player seals, originating probably in North Syria, and Euboean pendent-semicircle *skyphoi* and plates attest regular Greek contacts with Syria, the Levant, and the western coast of Italy during this period (Osborne 2007). The directions of trade, shipwrecks, and literary evidence in combination suggest that the Greek demand for minerals continued to dominate the exchange of goods abroad, while manufactured products, above all pottery and textiles, as well as slaves, perfume, foodstuffs, and a range of raw materials completed what were mostly mixed cargoes. Etruscan cities such as Caere, Tarquinia, and Populonia entered interregional trade by the end of the seventh century BCE with contacts concentrating around Massilia and along the southern coast of France (Dietler 2007: 248–250). Much of their activity seems to have been stimulated by the Greek colonists' demand for wine.

The texts of Homer and Hesiod help to understand the social organization of trade and exchange in the archaic period (Tandy 1997). Among the Greeks, most long-distance exchange of high-value goods seems to have been controlled by aristocratic landlords (*basileis*) and took the form of gift exchange in relationships of guest-friendship (xenia, Herman 1987). In addition, small local journeys were undertaken intermittently by well-off peasants, such as the Boeotian poet Hesiod, who had enough surplus to dispose of along the nearby coasts in the dead season after the harvest. While this so-called cabotage mattered little in terms of aggregate value in comparison with the large-scale ventures of

wealthy chiefs, it is assumed to have made up the bulk of archaic trade (Horden and Purcell 2000). A third type of trade was in the hands of professional traders. In the *Odyssey*, these are always foreigners (Phoenicians or "Taphians"; e.g., *Od*. 8.14 ff.), but the Greek trading settlements (*emporia*) abroad, such as at Pithecusae and, from the seventh century BCE onward, Naucratis (Egypt), Gravisca (Italy), Massilia (France), and Emporion (Spain), show that there were large numbers of Greek professional traders as well. These towns or settlement areas have been identified as trading diasporas of populations that had no social ties among the communities with whom they traded and interacted in special institutional environments (Curtin 1984). One such environment was the port of trade, best exemplified by the Greek town Naucratis in Egypt. This town in the west of the Nile Delta was granted by Psammetichus I to Greek traders in the last quarter of the seventh century BCE and served as an enclave for Greek communities who could establish here places of worship and markets. There is some indication that markets were strongly controlled by the host administration, partly to link different economic systems and languages (Möller 2000) but also for the purpose of taxation. In practice, these trading communities provided a breeding space for knowledge about interregional supply and demand (Osborne 2007). In archaic Naucratis, we find Chian chalices which seem to have been produced to order (Möller 2000: 136–140), while still in the fourth century BCE it was in Naucratis that a business consortium able to control grain trade and prices between Rhodes, Egypt, and Athens emerged (von Reden 2010: 131).

By the sixth century BCE, migration had dispersed Greeks in settlements around the Black Sea, Sicily, Southern Italy, and the southern coasts of France and Spain. Although the vast majority of these were dominated by agrarian subsistence economies, their urban centers created new demand for Greek products and a supply of raw materials and products from these areas at lesser costs. A series of technological changes both reflected and stimulated further the expansion of trade during the sixth century BCE. Firstly, the traditional Egyptian rigging with a square boom to which the sail was fixed developed into a loose-footed square sail fitted with brails at regular intervals. This made it possible to lift the sail up and shift it to the sides, which allowed full control over the sail according to the strength and direction of winds (Casson 1994: 43–44). Secondly, although some maritime installations are known from the Early Iron Age, the first permanent harbor facilities (breakwaters, ship sheds, and dockyards) appear in the sixth century BCE. There was at first no functional differentiation of military and commercial harbors. But other infrastructural innovations, such as the stone trackway (*diolkos*) for transporting ships and cargoes across the Isthmus of Corinth dating c. 600 BCE, show the general value attached to infrastructural improvement in the demonstration of power between individuals and poleis. The third technical innovation was coinage. Invented in Lydia at the end of the seventh century BCE, it soon spread into Greece where the first coins were struck by about 550 BCE. Monetary payment had been possible for centuries on the basis of bullion and ingots cut to size and certified by local temples, but coinage facilitated monetary transactions and at the same time created a new linkage between trade and the identity of *poleis* and their political allies (von Reden 2010). Gradually, moreover, coinage paved the way for greater monetary coherence and better comparability of prices and value.

The Athenian naval confederacy of 479 BCE was another influence on trade with enormous economic consequences. It began with the expansion of the Athenian fleet in the 480s that was possible only with the supply of an unsuspected windfall of silver from the Athenian mines minted into coinage and with the import of timber from foreign resources. It is unlikely that wood and pitch were imported into Athens via the market rather than through the channels of personal political guest-friendship ties which provided the elite with economic resources to be invested into social and political power (Herman 1987); but coined silver was certainly used for the payment of the labor force. There followed the fortification of the Piraeus at around the same time, and the Athenian control of the sea routes as an immediate

consequence of her sea power. Other consequences were more gradual: firstly, a massive expansion of Athenian coinage and the gradual supersession of competing, especially Aeginetan, coinages (Figueira 1998); secondly, the growth of the Piraeus into a central harbor and marketplace for Greek and foreign products; and thirdly, the emergence of Athens as a center of consumption at an unprecedented scale. The Athenian League was not a tributary empire where the power to extract goods and services in kind puts limits to the growth of trade. Instead, Athens' commitment to monetary payment stimulated trade and a larger amount of poleis and people to earn and spend money in markets. A substantial part of regular imports in Athens (and presumably other *poleis* of which we are less well informed) was grain with which the cities could compensate for recurring shortages of locally grown cereals and ensure the provision of better-quality wheat available especially from the Black Sea area. A host of other goods, both luxuries and semiluxuries (staples of better quality from elsewhere), made up the substantial volume of imports. Important institutions developed during this period (Bresson 2016). Money changers, followed by banks (*trapezai*), appear in the second and the last quarter of the fifth century BCE, respectively. Lending and borrowing for commercial purposes increased and led to the invention of a particular kind of maritime credit (*nautica daneia*; first attested in the late fifth century, Eup. *CAF* fr. 43). In such contracts, the cargo of the ship, rather than personal surety or landed property, serves as security for a loan. By 415 BCE, the revenues from harbor tolls, levied as a 2% tax on the value of the cargo, were so substantial both in Athens and the harbors of her allies that they could substitute for the tribute Athens was no longer able to extract. In the fourth century, maritime courts were established which provided quick solutions of legal conflicts under the special condition of foreigners being involved (Cohen 2005). For, despite the enormous economic importance trade had gained during the fifth century, both in aggregate value and in social terms, trade and banking was mostly in the hands of foreigners and resident aliens (*metoikoi*). Athens also tightened the control over its coinage to increase trust in what had become an interregional currency. In addition, we hear of the possibility of making monetary orders in writing to bankers in other places, which, though not being a proper form of giro, allowed the transfer of credit from one place to another (von Reden 2010).

The combined effects of the Athenian Empire, its silver resources, political organization (leading to particularly effective ways of collective decision-making and legislation), and commitment to coinage created an institutional structure for the development of trade in the following centuries. The Macedonians modeled their coinage and law on that of Athens and showed the same commitment to coinage and markets in their payment of mercenaries and the provision of military supplies via local markets. The Macedonian conquest of the Persian Empire also led to the foundation of new cities in which the Greek military settlers and civilians lived a markedly Greek lifestyle. At the same time, the Macedonian kings took over from the Persians a treasure and tribute system which put at their disposal levels of wealth incomparable to those of Greek *poleis*. The fusion of Near Eastern resources, Greek economic structures (including coinage), and the demand for Greek products outside the Greek mainland boosted the level of trade, measurable by the increase of sea travel, minting, and size of cities. Alexandria's total population is estimated at around 200,000 by the third century BCE, which is almost twice as much as the estimated total population of all Attica in the classical period and four times as much as that of the biggest towns of the former Persian Empire. The fact that the fabulous monetary wealth of the Ptolemies was dependent on silver that, because of the lack of silver mines in Egypt, must have come into the country by circulation shows that their prosperity rested as much on tribute as on export (von Reden 2007). A corollary of Alexandria's role in Mediterranean trade is the movement of the major port of transit from Piraeus to Delos by the end of the fourth and to Rhodes in the third and second centuries BCE, leading the Roman government to declare Delos a tax-free port in 166 BCE again. In much of Hellenistic trade, kings, their administrations, and

managers of royal estates were involved. But given that all of them acted in tandem with, and through, agents who pursued their own economic business at the side, it is impossible to disentangle fully trade under royal control from private enterprise. The link between private and public/royal enterprise and control is probably one of the reasons for grain prices staying at surprisingly similar levels from the classical through to the Roman period (Rathbone 2014). Given the unparalleled role of this staple for peace and prosperity, the grain supply of urban markets was a political issue influenced economically by kings, emperors, and local benefactors rather than the supply-and-demand mechanism. For other commodities traded in the Mediterranean, we are lacking the data to analyze price formation. But in the rare cases where this is possible, there seems to have been a regional, rather than a Mediterranean-wide, pattern (Reger 1994).

By the beginning of the third century BCE, the Romans had expanded their trading contacts into the Italian peninsula, the Western Mediterranean, and the Adriatic region. Greeks from Massilia, Northern Greece, and Phokaia had established in continental Europe from the late sixth to the fourth centuries BCE contacts which were dominated by some Italian imports, especially of wine and fine pottery, from the early second century BCE onward (Woolf 1998: 174–176). The end of the Second Punic War in 218 BCE created Roman hegemony over the Carthaginian sphere of influence in the West. Roman trade in the Adriatic in 229/8 BCE was conspicuous enough to suggest that the conflict with the Illyrians resulted from Roman intervention on traders' request against Illyrian piracy (Polyb. 2.2–6). The gradual increase of Roman participation in Greek trading networks is shown by the gradual spread of Roman amphorae into the Greek East, by commercial settlements of Romans and Italians on Delos and the presence of Roman merchants at Alexandria (Harris 2007). The most important effect of the expansion of Roman trade into the Greek sphere of influence was the spread of Greek financial sophistication into Rome and Italy (ibid.). Greek banking, credit operations, forms of monetary transfer, and transfer of debt claims to third parties became a vital condition for the economy of the Roman elite to function between Italy and the provinces (Andreau 1999). With the expansion of the Roman Empire, the scale of trade in the Mediterranean exploded (Wilson 2008). The number of shipwrecks dated to the period between 100 BCE and 300 CE is far greater than in the periods before and after, suggesting – despite some archaeological bias – a scale of maritime transport not reached again until the high Renaissance (Patterson 1998) or the nineteenth century even (Wilson 2008). Larger ships of 200–400 t were used more frequently. A certain type of amphora (so-called Lamboglia 2) produced in Apulia is now found everywhere in the Western Mediterranean, while some African amphorae occur on most sites between Britain and Egypt. Amphorae used in any type of interregional trade also became more standardized, which must be taken as another indicator for the regularity with which goods were moved (Morley 2007a). Access to new mines and foreign treasuries created a massive increase in the total volume of coinage circulating in the Roman Empire from the second century BCE onward. By the time of the first century CE, the Roman denarius currency had become an imperial coinage accepted throughout the Roman Empire (except Egypt), creating a fairly homogenous monetary zone. The growth of the city of Rome, finally, exceeded by far that of any royal capital in the Hellenistic world; this growth was demographically possible only if external resources kept pace with increasing consumption levels. The major zone of Roman trade was the empire, but there is now increasing research in Roman trade of considerable scale and value beyond the frontiers of the Roman world (Cunliffe 2015: 253–295; von Reden 2015; Wilson and Bowman 2018). Among the best attestations is the trade in spices, ivory, marble, and fine textiles with the east coast of Africa, as well as areas beyond the Red Sea and India (Tomber 2012; Cobb 2018).

The period from the late third century CE onward is generally regarded as a time of recession, distress, and transformation which affected trade in complex ways. There was recurring stress of the imperial currency and of enforcing central

law and taxation and a trend toward greater regionalization. As a result, the diversity of local economic situations becomes more visible, and there is a notable diversity of responses to central policy. There are, moreover, clear indications that the Roman government aimed to reduce the role of private intermediation in the trading of certain products, while maritime transport became a compulsory office (*munus*) rather than a profession left to private contractors (Giardina 2007). But there is as yet no clear indication that, despite changes in organization, the scale of trade declined in aggregate value. Moreover, answers to the question of the degree of change in late antiquity depend largely on how scholars assess the nature of the Roman economy in the preceding centuries. How much did trade conform to the model of an integrated market economy?

The first question to be addressed is whether in the first centuries of the Roman Empire there developed new structures of trade and finance. An increasingly differentiated system of banking and financial intermediation – most importantly, legally protected forms of cashless transfer of money over distance – emerged during the two centuries before and after the reign of Augustus (Andreau 1999; Harris 2007). But it seems fairly certain that any long-distance trade and transport continued to be based on midsize transport and maritime loans, while large-scale ventures were achieved by pooling the capacities of several financial and transport resources. Thus is the picture emerging from the evidence of maritime finance in the Roman empire (Rathbone 2003). Thus was also the strategy of Cato the Elder in the second century BCE who spread his credit among an association of 50 traders to reduce the risk of loss and increase his own profit (Plut. *Cat*. 21.6).

The second question relates to the system of exchange behind the movement of goods and money. According to an influential model, the Roman economy in the Mediterranean came to be more integrated than before through taxation, the requirements of the Roman army, and trade (Hopkins 1980). There was an uneven productivity in the provinces of the empire and an uneven demand for military supplies, since armies were stationed above all in the provinces at the frontiers, while the provinces with high productivity were those closer to the Roman center. Through monetary taxation, monetary army payment, and army supply via local markets, the Roman government mobilized a large amount of goods and money and thereby stimulated trade and a market economy. The model has been challenged on various grounds, for example, for its lack of consideration of economic activity that did not result, directly or indirectly, from the initiatives of the Roman state (Patterson 1998; Morley 2007a). Both the Roman and provincial elites, and the emperors themselves, had high stakes in long-distance trade in order to increase their wealth and dispose of their agrarian surplus. Though rarely running themselves financial business and trade enterprises, they participated in them through their agents, freedman, and slaves who were merchants, bankers, and business managers (Aubert 1994). Trade and financial business of the Roman elite, moreover, were inseparably intertwined with the financial administration of the provinces they governed (just as there was an overlap between the imperial economy and the economic business of the emperors), which makes it impossible to disentangle the interests of the state from private trade.

The third question is whether the Roman Empire was a single economic zone linked by price-setting markets. The empire-wide consumption of wine and its mass production for export in Italy, Gaul, and Africa have been at the center of intense research. Not only is the movement of these goods archaeologically well documented by the movement of amphorae but the production and distribution of wine, in contrast to that of grain, had always been in private hands and rarely been interfered with by governments. There does seem to be a notable increase of wine amphorae of provincial origin between 50 BCE and 100 CE that coincides with a decrease of Italian amphorae (both for wine and other agricultural products) during the same period (Panella and Tchernia 2002). But if Italian wine amphorae are taken as a category of their own, the coincidence is less marked, and it has been argued that the increase of provincial imports in Rome and elsewhere was driven by increased consumption rather than

price competition (Panella and Tchernia 2002). Moreover, the export of wine to provincial places seems to have petered out as soon as these places became able to meet new levels of demand by local production (Morley 2007a).

Future Directions

While the debates over the nature of markets in the Mediterranean are likely to continue, the future of research in ancient trade will lie in the analysis of the interdepence of trade at different scales (Wilson et al. 2012; Rice 2016). Thorough investigation of the institutional arrangements in which ancient trade and exchange developed is indispensable and will lead to a better understanding of the differences between ancient trade and trade in other periods and cultural contexts (Bresson 2016). Moreover, as global historical approaches and economic world systems analyses begin to influence research on Greco-Roman antiquity, the nature and consequences of trade across cultural frontiers receive increasing attention (Shaw 2009; Wilson and Bowman 2018; Cobb 2018; von Reden 2019).

Trade Beads in Historical Archaeology

Jonathan R. Walz
Department of Anthropology and Archaeology Program, Rollins College, Winter Park, FL, USA

Introduction

During the last five centuries, European trade beads markedly influenced political economies at multiple scales. Columbus introduced glass trade beads to the New World, and the Portuguese introduced later European beads to much of sub-Saharan Africa, beginning with coastal regions in West Africa. Indo-Pacific, or Trade Wind, beads already dominated the market for trade beads in the Indian Ocean region (Wood 2011) and, in Asia, as far north as Japan (Francis 2002). Bead production in Amsterdam, in Venice, and at locations in Bohemia gained momentum in the seventeenth century. The Dutch, Spanish, English, and French widely distributed European glass trade beads and exchanged them for desired items, needed services, and slaves in the lands bordering the Atlantic and Indian oceans. The Spanish

mission period in Florida (1633–1704) and the late seventeenth-century to eighteenth-century fur trade of northwestern North America are notable examples. Explorers, such as Richard Burton, and the European and Islamic inspired slave and ivory caravans of the nineteenth century circulated tons of European trade beads into East and Central Africa.

Definition

Beads are small ornaments used singly or in groups. They are suspended from the body as personal adornments, worn in the hair, or sewn onto clothes or household objects. Beads are made from a variety of natural and synthetic materials – for later periods, notably from glass – and meet a range of social purposes. Glass beads and beads of shell deserve particular attention from historical archaeologists. Due to their variety and ease of transport, Europeans and indigenous Americans and Africans exchanged beads, gave them as gifts, or used them as currency. Thus, beads are key indicators of contact and culture change. Non-Europeans often gradually adopted glass beads into their social practices and systems of status. For this and other reasons, archaeologists commonly find glass beads in burials at sites that postdate CE1500 in the Americas. Different European powers and people living in the Americas, Africa, and Asia produced and consumed different beads based on changes in access to raw materials, trends in production and technique, shifts in distribution networks, and local desires for specific bead types (e.g., Wood 2011).

Key Issues and Examples

Trade beads are particularly useful in historical archaeology, but they also present challenges (Spector 1976). Beads of glass, shell, and semi-precious stone tend to preserve well and may serve as valued chronological markers. However, beads tend to migrate across site strata and require detailed comparative study. At a minimum, bead analysis requires a classificatory system based on size, manufacturing technique, structure, shape, and color/diaphaneity (Kidd and Kidd 1970; Karlkins 1985; Wood 2011). For European glass trade beads, artisans used three primary techniques: drawing, winding, and molding. They made red, blue, black, white, and multicolor tubes, barrels, doughnuts, and spheres. In structure, European trade beads are simple (one color/layer of glass), compound (layered multiple glasses), or complex (with applique or inset decorations). Shell beads from the Americas, Africa, and elsewhere during the last 500 years frequently appear as discs or tubes. The great variation in bead types and their shifts in use indicate the prominent role of trade beads in the emerging social entanglements of regional and global exchange.

Tranquility Base on the Moon

Beth Laura O'Leary
Department of Anthropology, New Mexico State University, Las Cruces, NM, USA

Humans and our direct ancestors have been looking at the night sky for millions of years. Our gaze has been from the Earth to the heavens and to the very same face of the Moon, unchanged except for its natural cycles. Humanity has a collective heritage in space through many different perspectives. This heritage ranges from including the Moon as part of indigenous cultural narratives about creation (e.g., the Southern Tutchone of Yukon, Canada, who have a story about how crow stole the Moon and threw it into the sky) to tracking phases and the seasonal setting of the Moon in prehistoric observatories at archaeological sites such as Stonehenge in Great Britain. The Moon serves as a point of reference for community knowledge; it is a place where memories are stored. Space is not a vacuum but is part of humanity's cultural landscape that only began to acquire material culture, relatively recently, within the last 60 years. How to interpret the human interaction with space, what to preserve, and how to preserve it is to tackle a huge landscape layered with cultural, religious, historical, and scientific meaning.

This cultural landscape, or what Gorman (2005) has called a "spacescape," contains facilities on Earth such as launch complexes, manufacturing locations, etc., a lot of trash invisibly moving above us in Earth's orbit and a few spacecraft like *Voyager 1* which is in interstellar space. There are an estimated 500,000 bits of human-made objects in orbit. There are over 4635 satellites currently orbiting the planet and the amount increases every year (NASA (2018)). Unfortunately, nobody knows exactly the amount and what is up there. Other essential components of this cultural landscape are the archaeological sites on celestial bodies including the Moon, Mars, a few asteroids, and comets which have been visited by robotic spacecraft and, in some cases, by actual humans. The Apollo missions 11, 12, 14, 15, 16, and 17 created an array of archaeological sites where 12 humans walked and left artifacts and features on its surface.

The field of space archaeology and heritage began in 1999. It was driven by a question that was posed by then graduate student, Ralph Gibson, in my cultural resource management seminar at the New Mexico State University (NMSU). He asked if the federal preservation laws and regulations we were studying applied on the Moon. I had no idea, but it was a great question. It intrigued us enough to apply for funding from the New Mexico Space Grant Consortium (NMSGC), a NASA educational outreach program on the campus of NMSU. We had two questions in our proposal: What archaeological sites, artifacts, and features were on the Moon and what, if any, preservation laws applied to them? There is an amazing amount of cultural material (now over 200 mt) on the lunar surface, and there were surprising inadequacies in the documentary records. Because of the number of lunar sites, currently in access of 90, and the amount of material, we decided to focus our archaeological investigation on one iconic site – the Apollo 11's Tranquility Base, the first lunar landing site. That site represents the first visit of humanity to another celestial body. The NMSGC grant was in no way large enough to go back to the Moon for a proper archaeological survey, but the funding for what became known as the Lunar Legacy Project did allow for travel and research to libraries, museums, and facilities in Houston, Florida, and Washington DC in 2001–2002

(Lunar Legacy website). The Lunar Legacy Project along with subsequent conferences in the USA, Canada, Great Britain, and Australia, where groups of similarly minded scholars convened, has helped to define the field of space archaeology and heritage. A group of published seminal books (Schofield and Cocroft 2007; Darrin and O'Leary 2009; Capelotti 2009; O'Leary and Capelotti 2015; Westwood et al. 2017) defined the field of space archaeology and heritage as a subdiscipline of archaeology.

Archaeology is defined as the study of the relationships between patterns of material culture and patterns of human behavior. The definition of archaeology does not set any spatial limitations on the discipline. Archaeological investigations can be performed on any place where humans live or have lived; it is not limited to Earth. The human exploration of space allows for archaeological method and theory to be practiced there. Also there are no temporal limits. Beginning with the study of recent urban trash at Fresh Kills, New York, dating to the 1970s and the study of orbital debris (Rathje and Murphy 1992), archaeologists have studied the present or very recent past. The foundations of space archaeology and heritage are rooted in the work of the late Ben Finney, who explored the technology of the exploration and settlement of Polynesians in the South Pacific. He suggested it was equally important to think about space sites created by the USSR and the USA during the Space Age (Capelotti 2009).

The most complete definition of space archaeology and heritage is "the archaeological study of material culture, that is, exoatmospheric material that is clearly the result of human behavior" (Staski 2009: 19). Those exoatmospheric cultural materials are part of a larger assemblage of materials which until a certain point in time and technological development were confined to Earth but entered the archaeological record somewhere else (Staski 2009: 19). It encompasses all material culture that relates to the development and support of exoatmospheric activities and human behavior on the Earth, which is the place to which all space materials are tied. Space archaeology crosses a number of subfields such as historical, industrial, and science and technology studies (Gorman and O'Leary 2013). Critical to determining the significance of places and artifacts associated with space exploration is a description and understanding of the historical context in which these events happened. It is necessary to evaluate a place within its historic context.

The historical period tied to the exploration of space is a post-World War II phenomenon. At the end of the war, both the USA and the USSR engaged in a competition to obtain both German rockets and German rocket scientists. The V-2 rocket became the basis for Cold War (c. 1946–1989) missile technology, and its descendants launched the earliest satellites and later propelled humans to the Moon. The Cold War was played out in space as well as on Earth (Gorman and O'Leary 2007). It was a period that was materially represented by unprecedented development in rocket and weapon technology which was accompanied by massive military construction efforts (Schofield and Cocroft 2007: 13).

Although in recent history, the Cold War appears to be well documented, it was a time of great secrecy and evidence may be sealed in various state archives. The wealth of recorded data and accessibility to living memory can mislead historians, archaeologists, and historic preservationists into thinking that everything is known. The proximity of the Cold War period and the types of data also reveals a tangible sense of different viewpoints and perspectives and thus contested or conflicting interpretations which should force archaeologists, at least, to question assumptions about data and its use from earlier periods that are taken uncritically as givens (Fairclough 2007: 22). The Cold War can be viewed as a time of a western-led fairly violent trend toward the globalization that is experienced today.

The Cold War was a period of geopolitical tensions and what many historians describe as a standoff imposed by a global division between communism and capitalism. It is interesting that early events in space history consisted of amazing scientific and technological breakthroughs – such as leaving the surface of the Earth and going into outer space – coupled with militarization of a post WWII world. One such event reveals the origins of both the scientific and military aspects of how humans first landed on the Moon.

An international competition in the 1950s was part of the follow-up to the International Polar Years to include the study of Earth as a whole. The International Geophysical Year (1957–1958) challenged national participants to create a satellite which would circle the Earth. The winner was the USSR, who launched *Sputnik* in 1957. The excitement of the first entry into space was coupled with the fear of imminent military threats from space. While *Sputniks* circled the Earth, the USA had a series of what was termed "flopniks" until finally *Explorer I,* developed by the US military, went into orbit in January of 1958, followed by *Vanguard I* later that same year. All three satellites can be seen as ideological weapons, presenting space ambitions as scientific and peaceful while at the same time demonstrating technological superiority (Gorman and O'Leary 2007: 81). Space became a technological battlefield during the majority of the Cold War. While the S*putniks* have de-orbited, *Vanguard I* is still in orbit and is predicted to be there for another 600 years. It is currently the oldest human artifact in space (O'Leary 2015). As an object, it has both cultural and scientific significance and is a critical part of the material record that is the evidence for humanity's venture into space.

The new era which began with the launch of *Sputnik* has been called "the Space Race" within the Space Age. It set the stage for a successful manned flight to the Moon which would be considered a decisive win in the battle for a new territory during the Cold War. At its inception and as this race developed, the Soviets appeared to be winning. The race to the Moon had many stages. The early Soviet *Luna* robotic space missions were mostly successful with *Luna 2* landing in 1959 on the lunar surface at Mare Serenitatis where it delivered a Soviet pennant to the surface. It was followed less than a month later by *Luna 3,* which was the first spacecraft to return images of the lunar farside (Stooke 2007: 15, 17). The Soviet's *Luna 10* was the first robotic spacecraft to be put into lunar orbit in 1966, duplicated a few months later by the USA's *Lunar Orbiter 1*, designed to find suitable landing sites for the manned missions of the Apollo program.

The Apollo program rode on the successes of the earlier Mercury and Gemini programs, although getting humans into space was done earlier by the USSR. In spite of the tragic setback of Apollo 1 in 1967, the Apollo program surged forward with three critical missions of 8, 9, and 10 that set the stage for the first lunar landing by Apollo 11. There was a change in Apollo 8's mission from earth orbit to lunar orbit because of the word that the Russians were planning on going around the moon before the end of 1968 (Borman 2001). Even after Apollo 8's crew successfully located a place for future missions to land, the Soviets continue to plan manned lunar missions. Four Soviet un-crewed launches ended in disaster with the third Soviet launch failure occurring only 13 days before the scheduled launch of Apollo 11 (Chaikin 1994: 197).

The final stage for winning the space race was to claim the Moon by standing on it. The event happened on July 20, 1969 (Fig. 1). Although hailed even by Apollo 11 astronaut Armstrong as a ". . . giant leap for mankind," it was an American who stepped on the Moon with much of material culture put there symbolic of the United States' presence. Although the legal tenets of the 1967 Outer Space Treaty and the rhetoric of Armstrong's statement point to the ownership and achievement by humanity, planting an American flag was one of first activities the astronauts engaged in after landing (Gorman and O'Leary 2007: 84) (Fig. 2). The act, set by historic precedent, was symbolic of claiming territory and victory. To the Soviets, it must have signaled a defeat in space.

The Tranquility Base site where two humans landed and stayed for approximately 21 h is an archaeological site. The 6700 m^2 (1.66 ac) site is located at lunar coordinates 0.67266° N Latitude, 23.47298° E longitude (Stooke 2007) which can act as its archaeological datum point. It has over 106 objects and features like footprints and trails. An inventory, probably not complete, is on the Lunar Legacy website (Lunar Legacy website). Although the majority of artifacts evidence the technology of the era and are scientific in nature, some are commemorative and symbolic. One of the first acts required of the Apollo 11 astronauts

Tranquility Base on the Moon, Fig. 1 Boot and footprint of Apollo 11 astronaut on the lunar surface. (Courtesy of NASA)

Tranquility Base on the Moon, Fig. 2 Apollo 11 astronaut Buzz Aldrin and American flag on the lunar surface. (Courtesy of NASA)

after landing was to plant an American flag on the lunar surface. If an archaeologist were to actually visit Tranquility Base in the future, the assemblage would be viewed as American material culture with representations of the international community (Gorman and O'Leary 2007: 86). For example, at the site on the Lunar Excursion Module (LEM) descent stage called "the Eagle" in reference to America's symbolic bird, there is a plaque which includes the words ". . .We came in peace for all mankind." There are good will messages from 73 nations etched on a silicon disk at the site containing messages of humanity's endeavors for peace, although there is no message

from the USSR (Gibson 2001: 66). It is filled with what was cutting-edge technology at the time. For example, there is a "scong" which was invented for the mission, a combination scoop and tong to collect samples of regolith and rocks from the lunar surface. These samples provided dates to the geological sediments to between 3.6 and 3.9 million years. There is also an abandoned television camera which helped to broadcast the first images of the astronauts on the Moon. There are many prosaic items, too. Before taking off from the surface of the Moon, Armstrong and Aldrin were told to jettison objects and refuse from the *Eagle*. For a period of 8 min, they stood and tossed out things such as overshoes, empty food bags, emesis bags, the plastic covering of the American flag, and various canisters. They created a toss zone of artifacts in one-sixth the Earth's gravity.

Other symbolic items left on the Moon include a gold replica of an olive branch, a traditional symbol of peace, and a small woven Apollo 1 mission patch, commemorating astronauts, Gus Grissom, Ed White, and Roger Chaffee, who had perished in the 1967 test on Earth. There are also artifacts left there that continue to function in 2018. Put on site is the lunar Laser Ranging RetroReflector (LRRR) which was purposefully placed so that observatories around the world could exactly calculate, among other endeavors, the changing distances from the Earth to the Moon. This small piece of scientific equipment, left in situ, is still in use, as are other LRRRs on several Apollo lunar sites.

The site boundaries are essentially a portion of the lunar landscape encompassing the areas of use, discard, and foot trails around the LEM descent stage to the Little West crater. It is a site that is what could be called an "extreme" single-component site in that only two people created and spent a limited time occupying it and it has never been returned to. Tranquility Base can also be considered extreme because it was done by individuals doing fairly planned and scripted behavior to an event never been done before (O'Leary 2009: 762–763). The site was, to a large extent self-documenting, a rarity in archaeological investigations as a whole. The cameras as well as the written documentation made before, during, and after the site's occupation recorded a significant amount of information about the assemblage and the human behavior (O'Leary 2009: 762). However, many of the photos made on the lunar surface capture only one astronaut's perspective. Many still images of the site, taken at the time of the event, were made by Neil Armstrong because he held the camera. We see Buzz Aldrin from his perspective with only one shot of Armstrong reflected in Aldrin's space helmet.

Most maps of the site were created later by piecing together various photos and images at the time of the event. The maps have never been archaeologically field checked. Reliance on remote sensing technology such as satellite imagery has increased in all fields of archaeology as the data become more refined, and this holds for the Moon as well. Recently, the Lunar Reconnaissance Orbiter, as part of the LCROSS mission, was sent to map the Moon and has taken images of Tranquility Base using remote imaging techniques that have provided archaeologists with details about the site in its present condition, although the resolution is not quite what archaeological survey requires.

The lunar environment is fairly benign. Natural formation processes on the archaeological record are those that result from environmental conditions. Natural forces on the Moon include great swings in temperature between the lunar day and night, micrometeoroids, radiation, and static electricity, but the erosional forces on Earth such as wind, water, and human disturbance have not affected Tranquility Base's condition. Staski and Gerke (2009: 519) have argued that the underwater environment which, at one time, was perceived as hostile and not capable of being archaeologically investigated has been revealed, in many cases (e.g., ship wrecks), to enhance the integrity and preservation of its archaeological resources. This also seems true for the objects when they were collected on the lunar surface from the earlier robotic *Surveyor 3* site by Apollo 12 astronauts. Astronauts Conrad and Bean acted as the first lunar archaeologists. It is still unclear how the natural formation forces operating in outer space have changed the cultural material left for almost 50 years at Tranquility Base. That question is only

resolved by future visits and exploration of the site using sophisticated archaeological field methods.

The reasons for the historic preservation of Tranquility Base seem to be self-evident. The site represents the first time humans actually landed on another celestial body. Tranquility Base contains artifacts from the earliest period and time of development when humanity left the Earth to explore what has been called the "ultimate" frontier. As such it represents in many ways the beginning of the use of space and one of the places that are critical to the current uses of space in the global economy, especially in the field of navigation and communication. It took over 60,000 people, working remotely from each other, to put two people on the Moon, an endeavor that rivals any monuments created on Earth. Tranquility Base is the landmark in the field of space archaeology and heritage. Since the late 1950s, humans have launched spacecraft which have flown toward and past many celestial bodies. Eight of these have been orbited and seven have had landers along with other material culture on their surfaces (Earth's Moon, Venus, Mars, two asteroids 433 Eros and 25143 Itokawa, Saturn's Moon Titan, and comet 67P Churyumov-Gerasimenko). Other missions have collided with or crash-landed on celestial bodies.

In terms of its legal significance, Tranquility Base meets all the criteria for listing on the USA's National Register of Historic Places and meets the more exclusive criteria for listing as a National Historic Landmark or a place which represents some "great ideal" of the American people. It also meets the criteria for being part of the World Heritage List, a part of UNESCO's World Heritage Convention (WHC) for a group of sites exhibiting "outstanding universal value." However, the WHC does not directly address cultural resources in outer space. The larger question is not if Tranquility Base or why Tranquility Base is significant; it is how to best preserve a place that ranks as extraordinary in a bricolage of state, national, and international preservation laws. None of these legal entities specifically address historic preservation on another celestial body. Currently all space sites and objects exist in a kind of legal historic preservation void.

Activity in space is governed by several international conventions colloquially known as the Outer Space Treaty, the Liability Convention, the Registration Convention, and the Rescue and Return Agreement. All are silent with respect to preservation and protection of human cultural heritage (Hanlon and Gray 2017: We Mustn't Allow History and Humanity to fall through the Gaps between the Space Conventions. Unpublished Ms). The Outer Space Treaty, ratified in 1967, 2 years before the lunar landing specifies space as a global commons, and not subject to territorial claims. It also specifies that cultural material (in the language of the treaty – equipment and personnel) remains under the jurisdiction, ownership, and control of the nation that puts them there.

The work by many dedicated archaeologists and historic preservationists has taken a number of avenues which indirectly and directly preserve sites on the Moon. In 1984 the US National Park Service commissioned a "Man in Space" Historic Landmark Theme study that inventoried sites within the USA that epitomized the space program, in order to list them on National Register of Historic Places. It had a fatal flaw: it neglected to include or even advocate for the sites on the Moon which are the most critical element in making the sites that were listed significant.

In 2000, the Lunar Legacy Project tested US federal preservation law by approaching NASA, as the federal agency responsible for Tranquility Base, and the US National Park Service (NPS) Keeper of the National Register of Historic Places by proposing Tranquility Base as a National Historic Landmark (NHL). The request was rejected by NASA's Deputy General Counsel as contrary to the Outer Space Treaty and as being perceived as a claim of sovereignty over a location in space by the international community and by the Keeper of the National Register who determined as matter of policy that an NHL was an inappropriate designation. And the Keeper also felt that NPS did not have sufficient jurisdiction. This request was both surprising and threatening, but it did bring the issue of lunar preservation to the relevant US historic preservation authorities (O'Leary 2009: 777). This roadblock affects listing on the World

Heritage List because although the USA is a signatory as a state party, it can only nominate a site to the list if it is already listed as an NHL.

Two strategies followed the rejections by American authorities. One was to make the international community aware of the importance of the concept of space archaeology and heritage by bringing it to a series of conferences for the professional national and international archaeological community. There were symposia at two World Archaeological Congress (2003, 2008) where a space heritage task force was created and a resolution passed to recognize cultural resources and places associated with space exploration and three symposia at the Society for American Archaeology (2004, 2011, 2013), as well as the Theoretical Archaeology Group in Great Britain (2007) and the International Council on Monuments and Sites in Australia (2007). It was important to also inform the astronomical and space engineering communities at conferences at the American Astronomical Society (2001) and Johns Hopkins University Applied Physics Laboratory (2008, 2015). Fortunately, the US national and international media were interested in the subject, and space archaeology and heritage were enthusiastically covered. In 2012, when one of the iconic figures in the Apollo program, Neil Armstrong, died, the public began to realize an epic era was ending which it helped spur the recognition of the need for Apollo 11 landing site preservation.

The efforts on a local preservation level were also made by two states. In 2010 they include successful nominations of the objects and structures at Tranquility Base made to the California Register of Historical Resources and to the New Mexico State Register of Cultural Properties. It was followed by recognition of Tranquility Base by the Hawaii State Legislature in 2014. The reason for coordination with states was the realization that almost all states in the USA had a connection, through research, testing, and/or manufacturing, with putting the Apollo 11 astronauts on the Moon in 1969.

The professional and grassroots efforts seemed to influence NASA to begin thinking about how to address historic preservation on the lunar surface. Space exploration and development are still a functioning, ongoing, and increasingly complex system. NASA does not focus on preservation; it continues space investigation and engineering. What has also changed in the last decade is the increased commercialism of space. There is a new space race that has nationalistic interests but includes more participants with commercial interests. One new approach to space is the concept of personal space flight. It is possible to buy your way into space and participate in what has been called "extreme tourism." Although now canceled, beginning in 2007, Google has had an X Prize competition that offered a $30 million (USD) award for sending a robotic vehicle back to the Moon, with a $5 million (USD) bonus for taking a picture of an Apollo site there. NASA, recognizing the increased technical capabilities of spacefaring entities to go back to the moon, created an unprecedented document. In 2011 NASA had a panel, including the author, help draft a series of guidelines and recommendations for those entities going back to the moon (NASA 2011). Although they do not carry the force of law, the guidelines seek to avoid damage to US property, and they recognize that future visits could destroy the historic and scientific values of the artifacts. NASA (2011) recommends a higher level of protection for Apollos 11 and 17 (the first and last Apollo lunar sites). Since 1969 many nations, India, ESA, Japan, and China, among others, have landed or crashed robotic spacecraft on the lunar surface. NASA's guidelines (2011) are a giant leap in attitude and commitment by NASA to space heritage than its initial response to the 2000 query to make Tranquility Base a National Historic Landmark.

There are definite risks to returning to the Moon. Future landings robotic or with humans onboard could damage the physical condition of the sites, inadvertently or otherwise. Without a commitment to preserve significant space sites, they are vulnerable to adverse impacts in the future. Ironically, the landing of the first commercial robotic spacecraft would itself create a significant archaeological site. The challenge is to preserve the sites which contribute to humanity's space legacy.

In 2013 a bill, HR 2617, the Lunar Landing Legacy Act, which proposed to designate all Apollo sites as a series of national parks, did not make it out of US Congressional Committee (U.S Congress 2013). The bill is legally flawed. It does not address the interests of other nations that have visited or will visit the Moon and would be perceived as a unilateral US attempt to control property on the Moon. Work continues with professional archaeologists and historic preservationists and groups like For All Moonkind Inc., to find ways to internationally protect the cultural material on the moon. Tranquility Base is a place that falls outside both the normal spatial and temporal boundaries of humanity. It involves the recent past for which we don't have the luxury of much of a retrospective view. As a whole, sites and artifacts in space or on other celestial bodies are the outcome of many minds and involve large-scale international competition and cooperation. Their study belittles the idea that there is a single, simple true past. Humanity has put artifacts off the Earth and over the last 60 years has created an archaeological realm of space heritage. The Space Era, however it is defined chronologically, has not been well studied archaeologically. Outer space is no longer an infinitely large place empty of material culture, as it was before c. AD 1957.

In conclusion, most of the presentations I give on space archaeology and heritage usually include a slide of the Moon with images of McDonalds and Starbucks on the lunar surface to jumpstart the conversation about Moon's future and heritage values (Fig. 3). Over the two decades, there has been an increase in the number of all aspects of space study, as well as courses on space archaeology and heritage. Graduate studies have embraced the field and focus on many areas: what human-made objects are in space, how to address the architecture of space-related facilities, how to design an archaeological study of the International Space Station, what are the challenges of dealing with significant orbital debris and future missions in space, and how space influences and affects globalization and non-spacefaring nations and peoples. Finally and most importantly, there is a recognition that most space heritage properties are without heritage protection. The Moon, its landscape, and cultural material record offer insight into all human exploratory behavior. Space archaeology can offer ways to evaluate the significance of space cultural material and provide input into future mission design and planning to avoid adverse effects to important artifacts and places off the Earth. Today, we are indebted to

Tranquility Base on the Moon, Fig. 3 Images of McDonalds and Starbucks imposed on the lunar surface. (Revised image by Beth O'Leary, image courtesy of NASA)

space as it allows us to navigate and communicate on Earth. There will be new paradigms for archaeological research that will affect our investigations of how material culture is used to mediate humanity's engagement with space. The cultural landscape of space is huge, the technology complex and moving at an accelerated pace. We have an opportunity to pause and look back at the last 50 or so years and consider how to preserve an extraordinary time in human history.

Translation and Indigenization

Ian Lilley
Aboriginal and Torres Strait Islander Studies Unit, University of Queensland, Brisbane, QLD, Australia

Introduction

Translation, broadly speaking, lies at the heart of archaeology. Archaeologists translate their technical recordings of material finds and their contexts into understandings of past human thought and action. They translate the technical findings of other disciplines – geology, say, or physics – into

archaeological terms and vice versa. They also translate their work from one language to another, from Vietnamese to French, for instance. Finally, they translate their "technical talk" into lay terms for public consumption. This last is ultimately the most important, because without the understanding and support of the wider, nonprofessional community, it would be well-nigh impossible for archaeologists to access the sites and acquire the funding necessary for them to practice their craft. This entry concerns one special form of "translation for the public," namely, translation of archaeological approaches and results for Indigenous and other descendent communities. This kind of translation is often called "indigenization." It is special because the political and ethical dimensions of such translation are more pronounced than in other cases.

Definition

There are two basic forms of translation. The first is literal information transfer based on word-for-word interpreting. The second is literary transposition, which aims to convey the sense and sensibility of what is being translated, rather than a word-to-word conversion. According to Friedrich Schleiermacher, the nineteenth century German theologian who first drew the foregoing distinction, literary translation "moves the reader toward the writer," whereas literal interpretation "moves the writer toward the reader" (Schleiermacher 1813: 41–2, cited in Munday 2001: 28). The latter is obviously important; one cannot simply ignore the literal meaning(s) of the original words. Yet many translators and scholars of translation believe that it is even more important to capture coherently the significance or conceptual thrust of those original words taken as a whole rather than individually. Translation in this sense is seen as an original, creative act.

Translation for archaeologists working with Indigenous people actually entails something of both approaches, of "moving the (local) reader toward the (archaeological) writer," and "moving the (archaeological) writer toward the (local) reader." On the one hand, the archaeologist needs to know, as intimately as possible, the cultural context into which a translation is to be introduced so that the translation can be sufficiently culturally competent to be comprehensible to the target audience. On the other hand, there is no point in an archaeological intervention where the translation is undetectable, as many translations aim to be, so that the introduced material just slips unnoticed into the local cultural setting. The recipients of a translation need to "feel *das Fremde*," the foreignness, of the translation if it is to make a difference to them (Eco 2004: 192). As Eco (2004) recognizes, translation is thus not a matter of choosing between literalness or creativity or what Venuti in various publications discusses as "domestication and foreignization" (Munday 2001: 145–8). Rather, it is a matter of *negotiation* between the various parties involved.

Key Issues

The Problem of Negotiation

Any such negotiation is problematic because it must strike a delicate three-way balance between making something culturally competent and comprehensible, accurately representing the original meaning, and behaving ethically towards local perspectives. Misrepresentation of the original can be a "sin of commission" as well as omission, through mistranslation, oversimplification, censoring, or if one's "artistic license" drifts into editorializing. This is why it is often said that to translate is to betray – that it is impossible to translate something without betraying the truth of the original. Inadvertent betrayal is easy because it is often hard to divine the intention of the person who originally produced the words in question. If they are one's own words, it is one thing, but if they are those of another can be very hard to be confident that one's translation does in fact capture what was "really meant."

In translating archaeology for consumption by Indigenous people, there is also the issue of betraying the target audience, of behaving unethically towards local perspectives. This matter is not usually taken up by translators or scholars of translation other than those such as

Spivak (e.g., 1993) who are concerned with post-colonial politics. This betrayal can occur in either or both of two ways. The first is when archaeologists translate simply to impose their views more effectively on local people in a straightforward continuation of colonial domination. The second form of betrayal is more subtle. Its discussion is controversial, to the extent that it turns post-colonial wisdom on its head, and that is when archaeologists seek to make their translation "invisible" (Venuti cited in Munday 2001: 146) to its recipients. "Domestication," or what in other contexts is called seeking "resonance" (Lilley 2009), can in fact be insidious "colonization by stealth" rather than what it is presumably intended to be, namely, a strategy of decolonization, of making archaeology "community driven."

The Two-Way Ethics of Negotiated Translation

At root, archaeology is archaeology. The discipline is a theoretically and technically very broad church, and this is not the place to try to define it more closely. Plainly, though, it is not social work or community development work. Nor is it really able to be truly indigenized or domesticated: it is and in the final analysis will always remain part of the Western Enlightenment project. It can, however, be deeply sensitized to Indigenous perspectives and concerns while remaining true to itself. It must do both to be of interest and relevance to Indigenous communities. If it is not sensitized, it will not be culturally competent or comprehensible. Yet if archaeology betrays its own values by attempting to disguise if not eliminate its indispensible scientific basis, it will be without value to anyone, including Indigenous people, because it will not be able to offer anything that cannot be found elsewhere. If archaeologists cannot justify what archaeology is "for" without trying to pretend it is something else, Indigenous and other communities will not see any point to it (Sand et al. 2006).

A crucial question to ask at this juncture is how to advance a translational project in a manner that is ethical rather than just pragmatically effective in its approach both to the discipline of archaeology and to descendent communities. Ethics are central in the latter connection because encouraging people to "take archaeology into their lives" necessarily incurs some degree of change in their beliefs about their worlds. One must reflect in depth on one's rationale: why should I want to change people's minds in this way? What could possibly be the benefit for them? Would any such benefit outweigh any immediate or longer-term negative impact the changes might cause? A standard ethical checklist is a useful guide here. How does one's approach sit with questions of justice, autonomy, non-maleficence (doing no harm), and beneficence (doing good)? The critical thing to remember in making an assessment is that "the perfect is the enemy of the good." One will rarely, if ever, be able to develop an approach that gets a "perfect score" on all counts. Rather, one should aim for a negotiated settlement where everyone gets enough of what they need to satisfy the requirements they first brought to the negotiation (Eco 2004: 6).

Resonance

Conventional approaches to "translation as negotiation" usually seek to achieve what is known as "resonance" because a new perspective ostensibly "needs to be resonant with cultural traditions and narratives to be appealing" (Merry 2006: 39). Attempting to move the archaeological writer towards the descendent reader is undoubtedly seen to be more ethical insofar as it helps redress imbalances of power and reduces the conceptual violence done to local people. Anecdotally, at least some archaeologists seem to believe that this means they have to give up science and replace it with an application of archaeological techniques somehow shorn of the discipline's larger theoretical and methodological framework. Merry (2006: 41), paraphrasing Ferree, points out though that "resonant discourses are less radical than nonresonant ones... [so] resonance is a costly choice because it may limit the possibility for longterm change." This is because deeply ingrained traditions can profoundly restrict the negotiation, thus "ignoring the continual contestation over meanings, their ambiguity, and their susceptibility to change" (Merry 2006: 41).

On this basis, it can be contended that archaeologists should support "a more dialogic analysis

that sees the production of meaning as contested, shaped by both group conflict and by the internal dynamics of the discourse itself" Merry (2006: 41–2). Similar arguments can be heard from descendent communities. Even if local people are not interested in much (or anything) that archaeologists might say, they generally still expect archaeologists to "hold up their end" professionally and do reliable, scientifically credible archaeology. They emphatically do not want to see archaeological techniques applied in a theoretical and methodological vacuum in the hope that this or that empirical titbit might appeal to the local community or part(s) thereof. To paraphrase, the reaction is to ask why descendent communities should take archaeology seriously if archaeologists don't. If so-called professionals are not going to do proper scientific archaeology, why bother descendents with a half-baked version? What exactly do archaeologists stand for, if not the integrity of their discipline?

Archaeology will be much better placed to benefit from the intellectual and practical opportunities that dialogue can offer if archaeologists acknowledge rather than deny the inevitability of, first, some level of conflict or disagreement or dissonance between themselves and Indigenous people and other descendent communities and, second, the constant need to justify what constitutes best professional practice. To take full advantage of these insights, translation should ideally proceed from one particular end of a continuum of variation in the degree to which "local cultural forms and practices are incorporated into imported institutions" (Merry 2006: 44). The end from which the discipline should try to depart is hybridization, a negotiated form of syncretism "that merges imported institutions and symbols with local ones, sometimes uneasily" (Merry 2006: 44). Merry (2006: 48) portrays the resulting conceptual mergers as "thickly shaped by local institutions and structures." At the other end of the continuum, where many past and contemporary attempts at collaboration remained lodged, lies "replication," in which "the imported institution remains largely unchanged from its... prototype... [and the] adaptation is superficial and primarily decorative" (Merry 2006: 44). Replications are only "thinly adapted to local circumstances" (Merry 2006: 48).

Through Thick and Thin

It must be emphasized that nonresonant approaches do not have to be only "decorative. . .thinly adapted" replications. There are many ways to adapt "thickly" to local circumstances: archaeologists do not have to discard science, and local people do not have to give up their own understandings. Oral-historical and archaeological particulars do not have to match precisely to match effectively. Archaeologists should not feel obliged to prove the details of local narratives nor local communities to look to science to confirm their version of events. Such close congruence between accounts may be possible and even sought out in some contexts, but coherence of even profoundly divergent conceptions of the past can also be achieved at a more abstract, conceptual level. Archaeology and local narratives can agree, for instance, that certain broad forms of activity occurred, perhaps even in generically similar places in roughly equivalent sequences. We might see, for instance, shared interest in initial colonization, changes in specific technologies, introductions of specific domesticates or exotic fauna, or the presence or absence of ongoing population movement, perhaps to or from particular directions.

Thick links can also be created along ethical lines, by archaeologists and local communities accepting with humility and good grace rather than resignation or hostility what each may perceive as the other's willingness or unwillingness to vary or surrender certain aspects of their customary practice. A crucial aspect of this situation is archaeologists accepting that local people may be unwilling to share everything they know about the past, such as certain mythological accounts, genealogical details, or locations of particular sites or sorts of sites. Some archaeologists might believe that people will tell researchers everything they know provided the scientists ask the right questions in the right way and will accept what the researchers say provided the scientists use the right wording in the right language to explain themselves, thus enabling archaeologists to be

utterly familiar with local custom and practice. Language obviously plays a pivotal role in effective cross-cultural communication (Lilley 2009: 54–8), but in the end, no amount of eloquent translation or even fluency in local languages will convince people to divulge secret or sensitive knowledge they do not want to (or are not in a social or political position to) divulge. Nor will it make them accept archaeological interpretations they do not want to accept. Recognizing this fact rather than attempting to force the issue with locals or flagellating oneself or one's colleagues for failing to communicate effectively can go a long way towards creating a "thick" adaptation to local circumstances.

Meta-interests

One thing that should greatly assist all involved in this process of translation as negotiation is what observers as different as Andrew Fleming and Tim Ingold have identified as local people's and archaeology's shared interest in "the temporality of the landscape" (cf. Sheehan and Lilley 2008). Thus, Fleming (2006: 271–2, original emphasis) describes how archaeologists as well as native dwellers

> *work* in the field... in the open air. An outsider at first, the landscape archaeologist has no choice but to become engaged in the landscape, to become an insider as a consequence of acquired knowledge... Landscape archaeologists are not obsessed with the attainment of hard-edged objectivity always and everywhere, and our field discourse always and necessarily involves thinking about the intentionality and mindsets of people in the past'.

More lyrically, Ingold (2000: 189) understands that

> For both the archaeologist and the native dweller, the landscape tells – or rather is – a story, 'a chronicle of life and dwelling' (Adam 1998: 54). It enfolds the lives and times of predecessors who, over the generations, have moved around in it and played their part in its formation. To perceive the landscape is therefore to carry out an act of remembrance, and remembering is not so much a matter of calling up an internal image, stored in the mind, as of engaging perceptually with an environment that is itself pregnant with the past.

Coming to "translation as negotiation" from this shared "meta-interest" is surely key to the indigenization of archaeology.

Trezise, Percy

Noelene Cole
Department of Anthropology, Archaeology and Sociology, School of Arts and Social Sciences, James Cook University, Cairns, QLD, Australia

Basic Biographical Information

Percy Trezise (1923–2005), who became a pioneer of Australian rock art research, was born in 1923 and raised in country Victoria. He trained as

an RAAF pilot in World War II and after the war became a commercial pilot. Following a stint in the Kimberley flying for the Air Beef scheme, he moved to Cairns in 1957 to take up a position with Ansett Airlines. As a pilot for Ansett and the Cairns Aerial Ambulance, Trezise flew regularly across Cape York Peninsula, the Gulf of Carpentaria, and the Torres Straits, transporting freight and passengers to and from remote cattle stations, bush settlements, and Indigenous communities. In his spare time, he developed his skills as an artist and embarked on a parallel career as a landscape painter and author and illustrator of children's books.

Although not professionally trained in anthropology (or archaeology), Trezise developed a serious interest in Aboriginal culture as a result of his experiences in the bush and was inspired to read the Australian anthropological literature, including the publications of Donald Thomson and Ursula McConnel who had worked in Cape York Peninsula. In 1962 at Karumba on the Gulf of Carpentaria, Trezise met Dick Roughsey (1920–1985), a Lardil man from Mornington Island. This was the beginning of a lasting friendship and professional collaboration between the two men. After retiring from flying in the late 1970s, Trezise engaged full-time in rock art research, writing, and painting until his death in 2005.

Major Accomplishments

Trezise was introduced to Aboriginal rock art in 1960 when he investigated reports of rock paintings south of Laura, in a locality which came to be known as Split Rock. Thereafter, he made unofficial aerial surveys for likely rock art locations while flying over the spectacular escarpments and gorges of the vast belt of sandstone country between Cooktown and the Great Divide. He followed up these aerial observations with arduous dry-season expeditions (on foot) to the remote plateaux and escarpments to locate and record the art.

From the early 1960s, Trezise was a recipient of research grants from the Australian Institute of Aboriginal Studies (AIAS, now AIATSIS, the Australian Institute of Aboriginal and Torres Strait Islander Studies) to document rock art in southeast Cape York Peninsula, following recording methods developed by Fred McCarthy, then Principal of AIAS. Trezise mapped major rock art sites and localities across the region and applied his artistic abilities to produce annotated, scaled drawings of the art in its various techniques (painting, engraving, and stencilling). Knowledgeable Aboriginal people identified rock art subjects (motifs) which became the basis for his classification system. Trezise was the first to report and document the ubiquitous Quinkan spirit figures of the Laura sandstones and to characterize the area as "the Quinkan region." From the 1960s to c. 1986, following his fieldwork, he deposited (variously) photographic, print, audiotape, and graphic records at AIAS/AIATSIS.

Without Dick Roughsey's assistance, it is unlikely that Trezise would have gained the trust of senior Aboriginal men (including Willy Long, George Pegus, Harry Mole, Caesar Lee Cheu, and Mitchell McGreen) whose contributions were crucial to his research. The men led Trezise to sites, provided insights into Aboriginal culture and rock art, related their traditional stories and languages, and narrated personal accounts of the devastating impacts of white colonization on Aboriginal people. As well as contributing to survey and recording in the Quinkan region, Dick Roughsey, who became a distinguished artist and public figure (he was awarded an OBE in 1978 for his services to Aboriginal art and culture), worked with Trezise in documenting the Lardil culture of Mornington Island (Roughsey 1975). With Wally O'Grady of the Cape York Conservation Council, Trezise and Roughsey lobbied state and commonwealth governments for the conservation and protection of Quinkan rock art. As a result of their extended campaign (see Trezise and Roughsey 1975), the Queensland government created the Quinkan Reserves and introduced cultural heritage management strategies in the region. Trezise's efforts also led to the Commonwealth government listing of "Quinkan Country" on the Register of the National Estate. In Cairns, he played a major role in preventing the establishment of a wood chip industry in the North Queensland rainforests.

Trezise's first major publication, *Quinkan Country* (1969), was intended for a general audience but was reviewed favorably in academic circles. According to MacIntosh (1970: 83) "(*Quinkan Country*) opens up an area practically untouched previously, for studies in Australian prehistory." Trezise's (1971) monograph *Rock Art of South-east Cape York Peninsula* was seminal in Australian rock art studies, and its classification scheme provided a basis for later typological analyses of Quinkan rock art. Trezise published numerous articles and papers, and his final account (Trezise 1993) presents an overview of a lifetime in rock art research. Some of Trezise's theories on Australian prehistory were controversial, e.g., his identification of extinct fauna in Quinkan rock art.

From the outset of his research, Trezise assisted, consulted, and worked with archaeologists and rock art specialists who came to work in the Laura/Quinkan region, including Richard Wright, Andrée Rosenfeld, Josephine Flood, Mike Morwood, Alan Watchman, and the author (NC). He was instrumental in having European rock art specialist Andrée Rosenfeld and her colleagues undertake the Early Man excavation in the early 1970s, a project which provided solid evidence for the late Pleistocene origins of Quinkan art. Stylistic analyses of Quinkan rock art conducted by Rosenfeld and other archaeologists have been much reliant on Trezise's graphic records.

In 1998 Trezise donated his personal archive of records to James Cook University, Cairns. In his lifetime, Trezise received various awards, including a Churchill Fellowship in 1972 for overseas rock art studies and an Order of Australia in 1996. In 2004, he was awarded an Honorary Doctor of Letters degree from James Cook University for contributions to Aboriginal studies and conservation. Trezise's legacy includes his many publications, a substantial rock art archive, and a body of ethnographic and ethno-historic work which is highly regarded (and often cited) by anthropologists and others preparing Aboriginal land claims and native title applications (Cole 2011).

Trigger, Bruce Graham

Thomas Patterson
Department of Anthropology, University of California, Riverside, CA, USA

Basic Biographical Information

Archaeologist, historian, theorist, activist-critic, Bruce Graham Trigger was born on June 18, 1937, in Preston, Ontario, and died on December 1, 2006, in Montreal, Quebec. He received his undergraduate education at the University of Toronto (B.A. in anthropology, 1959) and took his doctorate at Yale University (Ph.D. in anthropology, 1964) studying under George Murdock and Irving Rouse. He taught briefly at Northwestern University before joining the faculty of McGill University in 1964 as an Assistant Professor. He rose quickly through the ranks, promoted to Associate Professor in 1967 and then Professor in 1969. He was appointed the James McGill Professor of Anthropology in 2001.

Trigger was the recipient of numerous honors and prizes. He was a fellow of the Royal Society of Canada (elected 1976). He is the recipient of the Canadian Silver Jubilee Medal (1977), the Cornplanter Medal (1979), the Innis-Gérin Medal, Royal Society of Canada (1985), and the Prix de Québec (1991). In 2001 he was made an Officer of the National Order of Quebec and in 2005 an Officer of the Order of Canada for his sustained contributions to the social sciences. He received honorary degrees from the University of New Brunswick (1987), University of Waterloo (1990), University of Western Ontario (1995), McMaster University (1999), and the University of Toronto (2003). He was an honorary fellow of the Society of Antiquaries of Scotland (1981) and an honorary member of the Prehistoric Society (UK) (1991).

Trigger's contributions span the entire range of archaeological theory and practice. He carried out archaeological investigations in Egypt, Sudan, and Canada (e.g., Trigger 1965). He wrote extensively about the Huron and other First Peoples in Canada and their historical relations with early European settlers (e.g., Trigger 1976a). His study of the development of the concept of sociolcultural evolution (Trigger 1998) over the last three centuries and his writings on other theoretical topics (e.g., Trigger 1978, 2003a) stand as models of meticulous argumentation and clarity. So do his scathing commentary and criticism of universities that succumbing to pressures by the New Right have increasingly allowed business interests and government agencies to set their agendas and put profits ahead of open, critical thought (Trigger 1992).

Major Accomplishments

Trigger's archaeological writings move seamlessly from his monumental histories of archaeological thought through his analyses of contemporary issues in archaeological theory and praxis to his comparative studies of the rise of early civilizations. His histories were written at different scales. In some instances, he used a microscope to prepare a fine-grained analysis of the life and thought of individuals like Daniel Wilson or V. Gordon Childe (e.g., Trigger 1966, 1980a). In other instances, he peered through a somewhat wider lens to discern how particular patterns in the mosaic of archaeology appeared in the past and have developed along different pathways to the present day – such as nationalism, romanticism, or regional research traditions (e.g., Trigger 1984, 1995). Finally, in the two editions of *A History of Archaeological Thought* (Trigger and Glover 1989, 2006), he stepped back to see the larger picture composed of the mutual interactions and interconnections of the parts with one another and with the wider whole as these developed through time; here, the fine-grained texture derived from studying individuals or regional traditions is replaced by perspective, understanding, and appreciation of the totality as a whole.

Archaeology, for Trigger (1981), is an historical science. Consequently, his discussions of contemporary archaeological theory and praxis, their

connections with other disciplines, and their relations to the wider social concerns were typically framed in terms of conception of society and history that viewed them as processes involving emergence, formation, reproduction, and transformation. This was a dialectical conception of society and history that was finely tuned to structural inequalities (e.g., Trigger 1976b). He appreciated the significance of structural inequalities: the diverse understandings (standpoints) that groups with different relations to power have of society and the contested terrains of debate that occur as a result. It was apparent in his writings about ancient societies, how archaeologists understood and wrote about those societies, and how native peoples responded to those interpretations. This was perhaps most evident in his writings about the relations between archaeologists and native peoples – especially "Archaeology and the Image of the American Indian" (Trigger 1980b), "The Past as Power" (Trigger 1985), and "A Present of Their Past? Anthropologists, Native People and Their Heritage" (Trigger and Glover 1988). He believed that the accumulation of knowledge had potentially transformative effects, and his writings on the historiography of the relations between First Peoples and European settlers have had a profound effect on the way Canadian history is taught today.

Trigger's approach to archaeology was systematically comparative. This was as true of the collections he coedited with Ian Glover on regional traditions of archaeological research for *World Archaeology* (Trigger and Glover 1981, 1982) as it was of his *Understanding Early Civilizations* (Trigger 2003b). Here, he was less concerned with the rise of civilization per se than with understanding how the sociopolitical organization, economy, and cognitive and symbolic aspects of early state-based societies were articulated with one another; how these articulations came into being as earlier social institutions and practices were distorted, dissolved, and soon replaced by emergence forms; and the ways in which they provided the social cement that at least temporarily held together these structures of inequality. He paid close attention to the diversity of early civilizations, since he was well aware that they were not all the same. The book's wealth of empirical detail is matched by that of its theoretical underpinnings and comparisons of the standpoints different archaeologists have put forth concerning the rise of civilization. It is easy to imagine the debates Trigger was having with different colleagues and shows that knowledge is produced not merely through the accumulation of more facts but also honing and refining the frameworks we use to understand them.

Trinh, Hiep Hoang

Hiep Hoang Trinh
Institute of Archaeology, Vietnam Academy of Social Sciences (VASS), Hanoi, Vietnam

Basic Biographical Information

Hiep Hoang Trinh holds a Ph.D. in Archaeology from Vietnam Ministry of Training and Education; an M.A. in Archaeology from the University of Social Sciences and Humanities, National University, Hanoi; and B.A. in History from Hanoi University. He is the principal researcher and head of the Department for Metal Age Studies at the Vietnam Institute of Archaeology of the Vietnam Academy of Social Sciences (VASS).

Major Accomplishments

Since 1995, his work at the Institute of Archaeology has focused on several research areas such as pre-protohistorical archaeology of northern Vietnam, pre-Dong Son cultures in northern Vietnam, Neolithic and Metal Age cultural interaction between northeast Asia and northern Vietnam, and ancient social networks.

Tsuboi, Shogoro

Katsuyuki Okamura
Higashi-Yodogawa Research Centre, Osaka City Cultural Properties Association, Osaka, Japan

Basic Biographical Information

Shogoro Tsuboi (1863–1913) was one of founders of Japanese anthropology and archaeology. He was born in Ryogoku, Tokyo, in 1863. He entered Tokyo University to study biology in 1883 and established the *Society of Anthropology* with his friends the following year. In 1886 he started publishing the "Anthropological Report" (presently known as the *Journal of the Anthropological Society of Nippon*). He studied abroad for three years, in the UK and France, from 1889. Returning to Japan in 1892, he became a professor at the National University of Science (later, the Department of Science, Tokyo University) and the following year, founded the first anthropology class in Japan. Dr. Tsuboi produced a number of excellent students in various disciplines, including anthropology, ethnology, archaeology, and geology. In 1899 he obtained a doctorate of science from Tokyo University. He died in 1913 while attending the Fifth Congress for the Union Académique International (UAI) in St Petersburg, Russia.

Major Accomplishments

Besides being a child prodigy, Shogoro Tsuboi liked collecting, observing, and sketching whatever he was interested in. He also began publishing a journal and setting up study societies as early as his teenage years. In 1883 he wrote his first essay titled "Consideration on Pottery from Meguro Village." After that, he wrote energetically for a variety of academic fields covering anthropology, ethnology, archaeology, folklore, and modernology (the study of modern social phenomena). Over his lifetime, he wrote more than 1,000 essays for a variety of books and magazines for the general public as well as for academic journals published by organizations such as the Tokyo Anthropological Society and the Anthropological Society of Nippon.

In the field of archaeology, besides studies covering all prehistoric times, Shogoro Tsuboi worked particularly on the manners and customs of ancient Japanese people, Ainu culture, *haniwa* figures, and ancient Egyptian culture. Among his numerous works, three stand out as his major contributions to Japanese archaeology.

Shogoro Tsuboi's first major accomplishment was the discovery and identification of Yayoi pottery, later associated with the culture of the first period of farming in Japanese. In 1884, Dr. Tsuboi and his friend recovered an unknown type reddish pot from the Mukogaoka shell mound in Yayoi-cho, Tokyo. They found it to be totally different to

Jomon pottery in style and decoration and named it "Yayoi"-type pottery after the place name of its discovery while placing it chronologically between pottery of Jomon and Kofun (burial mound) periods.

The second major accomplishment of Shogoro Tsuboi involved the genesis of scientific research and reporting on burial mounds. In 1886 he conducted a very systematic and elaborate excavation of burial mounds in Ashikaga Park, Tochigi. He recorded and sketched in situ every object in the stone chambers as well as the mound. He then published "An excavation report of Ashikaga burial mounds," which had a great impact, not only on later studies of burial mounds but also on excavation methods and techniques in general.

Thirdly, Shogoro Tsuboi did much to vitalize the fields of archaeology and anthropology through academic debates. Among them, the most well known is his "Koro-Pok-Guru" hypothesis. In 1887, Tsuboi proposed that the "Koro-Pok-Guru" (small people from the folklore of the Ainu people of the northern Japanese islands) were the original people of Japan. This initiated a hot discussion on the origin of Japanese people and culture, with his views pitted against those of scientists who supported the hypothesis that the Ainu were the original people. This debate continued until Tsuboi's death in 1913.

Shogoro Tsuboi not only promoted academic fields but also disseminated scholarly knowledge energetically to the general public through plain and clear explanations and with public lectures, sometimes in cooperation with Mitsukoshi Department Store. He loved objects, people, and humor and created a grand network of colleagues with the same interests. He was a titan of knowledge in the liberal atmosphere of the Meiji Period and may be called the first practitioner of public archaeology in Japan.

Tsude, Hiroshi

Takehiko Matsugi
Okayama University, Okayama, Japan

Basic Biographical Information

Hiroshi Tsude is a Japanese archaeologist and historian. He was born in Osaka in 1942. He graduated from Kozu High School and entered Kyoto University to study archaeology under mainly Yukio Kobayashi, who was famed for his empirical research on chiefly tombs and society in Kofun period. After his undergraduate studies, Hiroshi Tsude worked as a research associate at Kyoto University, when he excavated several tumuli in Otokuni district, Kyoto prefecture, to launch his own research of Kofun period.

In 1977 Hiroshi Tsude was appointed to the post of Associate Professor of Shiga University near Kyoto. Shortly thereafter, he moved to Osaka University. As an Associate Professor in the Department of Japanese History at Osaka University, Dr. Tsude fostered many archaeologists working on the Yayoi and Kofun period prehistoric periods in Japan through his research and education. Dr. Tsude continued this work until his retirement in 2005. He was promoted to Professor of the newly established Department of Archaeology at Osaka University in 1988, and the following year, he obtained his doctoral degree in archaeology.

In 1989 Hiroshi Tsude received the Seiryo Hamada award, an award which is regarded as most honorable among Japanese archaeologists and historians.

Major Accomplishments

Hiroshi Tsude has made significant theoretical and practical contributions to the studies of social development and state formation in Japan through his use of Marxist theory and of an anthropological approach based on archaeological analysis.

Early in his career, Dr. Tsude attempted to reconstruct the development of an agricultural society in the Japanese archipelago. He undertook a Marxist analysis of iron farming implements, settlement systems, regionality of pottery in the Yayoi period, and reconsideration of farming families and their land ownership and published this in the volume *Nihon noko shakai no seiritsu katei* (*Formation Process of Agricultural Society in Japan*, see Tsude 1989). In the late 1990s, Dr. Tsude centered his research study on chiefly tumuli in the Kofun period. He attempted to reconstruct the political relationships among chiefs buried in these tumuli through a comparative analysis of the size and shape of the mounds and coffins and typological study of their offerings. This analysis was published in *Zenpokoenfun to Shakai* (*Keyhole Shaped Tumuli and Their Social Background*, see Tsude 2006). In this work Dr. Tsude argued that the Kofun period (third to sixth centuries) was an early state in Japan. This stimulated widespread discussions about state formation processes in prehistoric Japan.

Tupi-Guarani Archaeology in Brazil

Rafael Guedes Milheira[1] and Paulo Deblasis[2]
[1]Laboratory of Research in Archaeology (LEPAARQ), Department of Anthropology and Archaeology, Federal University of Pelotas, Institute of Human Sciences, Pelotas, Rio Grande do Sul, Brazil
[2]Museu de Arqueologia e Etnologia (MAE), Universidade de São Paulo (USP), São Paulo, Brazil

Introduction

Tupi-Guarani archaeology is one of the most studied themes in Brazil and South America, mainly because of Tupi-Guarani-speaking peoples, living along the Atlantic coast, were among the first contacted by Europeans around 1500 CE. Because of this early historical contact, a massive written record has been created about these Indigenous peoples. Ethnohistorical and ethnographic records provide a picture of the Tupi-Guarani as living in large villages organized in regional chiefdoms commanded by political leaders (*caciques*) and shamans (*pajés*). Their economy was heavily based on slash-and-burn agriculture (maize, manioc, beans, and squash, among many other crops), but hunting and collecting have always remained vital. The practice of war and anthropophagy has decisive social significance as a means of acquiring status and power as well as expanding territories through conquering, establishing political alliances, and, mainly after contact, enslaving other peoples.

From an archaeological perspective, the continental occupation of the Tupi-Guarani-speaking

peoples can be understood as long-term history, a formidable demographic expansion that interacted with other cultures from prehistoric times until today. The principal question for archaeology is, then, to understand the origins of the Tupi-Guarani culture and establish the archaeological correlates for such a deep historical process.

Definition

The Tupi-Guarani live in several groups and have more than 30 closely related languages. They are widely dispersed in the tropical and subtropical lowlands, a polygon that involves Brazil, southern Venezuela, eastern Peru and Bolivia, Paraguay, northern Argentina, and Uruguay. Although demographic data are unclear, there are estimates up to one million Tupi people just before contact (Fausto 1992: 382–383). Nowadays, Tupi-Guarani speakers compose no more than 250,000 people.

Key Issues and Current Debates

Despite the friendly first contacts with the Portuguese and other Europeans, the Tupi soon faced the hardship of slavery and genocide wars, as in most places of the New World. Even so, their widespread language and culture have provided common linguistic grounds (the *nheen gatu* or "general language") for the Jesuit and Portuguese expansion in the South American hinterland and have been persevered, throughout historical times, to this day.

Noelli (1993) has detected two academic trends in Tupi-Guarani archaeology, which he has named *ethnological imperialism* and *archaeological domain*. The first is related to ethnographers like Ehrenreich, Von Martius, Métraux, von den Steinen, Nimuendajú, and d'Orbigny, who synthesized written and iconographic historical documents from the colonial period (made by travelers, missionaries, and military) and which were sometimes supplemented by ethnographic observations. These approaches were accompanied by linguistic studies and focused on defining cultural traces and explaining the migratory waves across the continent. It did not take long to realize (e.g., by the accounts of the Jesuit priest Montoya and the French chronicler Jean de Léry) that the correlation between the geometric polychrome-painted style of pottery production and Tupian-speaking groups, highlighting the archaeological dimension of the Tupi-Guarani history.

One of the most important researchers of this period is the French ethnographer Alfred Métraux. His assumptions became rather paradigmatic and have had a strong influence on archaeological research, particularly as regards three focal points: (1) The Tupi-Guarani people's permanent search for the "land without evil," historically known as *yvy marane'y* in Tupian language. This ideology would explain the spreading out of the Tupi expansion throughout South American lowlands. (2) The polychrome pottery style would be linked to the Tupi-Guarani culture, thus indicating the extent of the Tupi-Guarani territory before contact (Métraux 1948). (3) The existence of a cultural boundary somewhere in the area of what is today the state of São Paulo, in Brazil. Such a linguistic boundary separates the Tupi peoples to the north from the Guarani speakers to the south. This linguistic and cultural split would inspire archaeologists to look for differences in technology and style of pottery (Fig. 1).

The beginning of the *archaeological domain* is related to the implementation of the National Program of Archaeological Research (PRONAPA), a research project with continental dimensions, coordinated by Betty Meggers and Clifford Evans, from the Smithsonian Institution in the USA, between 1965 and 1970. The PRONAPA, aiming at the large-scale mapping of archaeological cultures (organized in traditions and phases) by its material (mostly ceramic) correlates, has emphasized cultural (material) sequencing and did not put much effort in anthropological or linguistic perspectives. In this sense, the Tupi-Guarani tradition was considered "(. . .) a cultural tradition characterized by corrugated, brushed and polychrome pottery (red and/or black under engobe white or red), secondary burials in urns,

Tupi-Guarani Archaeology in Brazil, Fig. 1 Métraux (1927) expansion model for the Tupi-Guarani (Modified from Fausto 1992: 384)

polished stone axes and the use of *tembetás*" or labial adornments (Chmyz et al. 1976: 146). This dissociation of archaeological material culture from precolonial times and the ethnohistorical and ethnographic record of the (still alive) Tupi speakers has not taken into account the continuity of Indigenous historical processes and has disarticulated the perception of the native peoples' rights, with political consequences (Noelli 1993). This approach changed only after the 1980s when Brochado (1984), articulating radiocarbon chronology, archaeological, ethnohistorical, and linguistic data, sought a vertical historical long-term perspective relating the archaeological past to living native societies and ultimately recognizing that undertaking Tupi-Guarani archaeology in Brazil is to make Indigenous history.

In spite of its merits, the continuous-historical model suggested by Brochado (1984) has received several critiques as regards the relationships between archaeological cultures and ethnic groups. According to Lima (2011), it contributes to the conception of ethnic groups as internally homogeneous, historically continuous, and externally defined by cultural and linguistic characteristics. In the same way, according to Schiavetto (2003), the continuous-historical model has depicted the Tupi-Guarani culture as a homogeneous block unalterable and static, resulting from the indiscriminate use of archaeological, ethnohistorical, and ethnographic sources. Following this perspective, the continuous model has no resonance of contemporary cultural diversity, as considered from an "emic," fluid, and the dynamical concept of culture; thus, a variety of "peoples" would hide behind ceramic and linguistic continuity. The debate continues.

Another research focus is the origins of Tupi-Guarani culture, in both cultural and geographical terms. Based on the historical migrations of Tupi-

Guarani recorded by chroniclers and voyagers, Métraux (1927) proposed one of the first models in the twentieth century, suggesting the watershed of Paraná-Paraguay as the provenience area, with a migratory movement from south to north shortly before the arrival of the Europeans. More recently, Meggers (1987) suggested that the origin of this culture would be located somewhere on the Madeira River, with migrations to the south and, later, to the north. Following Métraux, Meggers also considered the Tupi-Guarani movement fast and relatively recent, around 500–1000 CE. From the point of view of historical linguistics (based on lexical-statistical method), Rodrigues (1964) suggested that the origin of the Proto-Tupi culture could be the region between the Madeira and Xingu rivers in the southwestern Amazon around 3000 BCE, with further developments and ramifications as they expanded to the east and south, acquiring distinct cultural characteristics.

Brochado (1984), following Lathrap's (1970) "cardiac model" (the idea that the Amazon was a radiating center of cultures), considers that the origins of the Proto-Tupi-Guarani are related to the Amazonian Polychrome Tradition. From the central Amazon, around 3000 BCE, demographic pressure would lead to a process of differentiation and expansion in two migratory waves. The Guarani went south via Madeira-Guapore watershed, ultimately reaching the Paraná-Paraguay Basin, being already well established around 100 BCE. Afterward, the Guarani reached the Atlantic coast in successive expansionist movements along the lower Parana (Plata) basin, turning north along the shore. On the other hand, around 500 BCE, the Tupi culture would have gone down the Amazon River to its mouth, in a movement from the west to the east, reaching the northeastern shores of Brazil, and then turning south along the coast (where they are usually called Tupinambás). This migration would have been linear and fast, following the Atlantic coastline. About a few hundred years before the arrival of Europeans, these two opposite migratory waves would have met, configuring a boundary around southeastern Brazil (Fig. 2).

Tupi-Guarani Archaeology in Brazil, Fig. 2 The expansion routes of Tupi-Guarani, with Tupi and Guarani global areas (Modified from Noelli 2008)

Tupi-Guarani Archaeology in Brazil, Fig. 3 (**a**) Typical Tupinambá-painted vessels with square and elliptical shapes from Araruama, Rio de Janeiro, Brazil (photo Beto Barcelos). (**b**) Typical Guarani-corrugated vessels with complex shapes from the Collection of Farroupilha Museum, Rio Grande do Sul, Brazil

Brochado (1984) and others have identified discrete stylistic differences between Tupi-Guarani pottery assemblages from the southern and northern parts of the country, in close correspondence to the linguistic boundary between the Guarani and the Tupinambá, respectively. Synthetically, Tupinambá ceramics are painted with geometric designs in red, black, and orange, with white or red engobe, in close proximity to the Polychrome Tradition in Amazonia. Tupinambá paintings are extremely well done, with technical refinement and accuracy. On the other side, the southern set called Guarani tradition covers part of the states of São Paulo, Paraná, Santa Catarina, Rio Grande do Sul in Brazil, as well as Uruguay, Paraguay, and the region of northern Argentina. The finishing style of Guarani pottery is predominantly plastic (although painted motifs are always present) with a strict set of vessel shapes and sizes. Pottery decoration employs a variety of finishing techniques such as smoothing, corrugating, ungulating, painting, brushing, slotting, and different kinds of incisions. Despite these differences, it is clear that they belong to the same cultural tradition. In both traditions, the enduring sophisticated iconography suggests enduring teaching-learning relations involving both experienced and beginner potters (Fig. 3).

Noelli (2008), following Brochado's model, states that the Tupi-Guarani culture has its origins in a wide region in the southern Amazon area, a polygon to the south of the middle and lower Amazon, between Tocantins and Madeira/Guapore rivers. This proposal was strongly debated by Fausto (1992), who adopted Métraux's ideas about a territorial expansion from south to north. Moreover, Buarque (2009) has dated Tupinambá sites in Rio de Janeiro coast around 900 BCE, suggesting that the territorial expansion of Tupi-Guarani was older than archaeologists had thought so far and that the origins of this culture should not be in the north, but rather toward southern Brazil. So, up to this point, there is still no consensus about the origins of the Tupi-Guarani culture and its obscure relationships with Amazonian polychrome tradition. From a cultural perspective, both models provide the Tupi-Guarani archaeology with an important sociological foundation, explaining the continental scale of the Tupi-Guarani territorial dispersion as a result of a diachronic historical long-term process of demographic expansion, only disrupted by the European conquest.

The Tupi-Guarani culture expands itself by splitting villages into cells systematically subdivided over time. This process, called "swarming" by Brochado (1984), produces a radial expansion of the territory in gradual population waves, thus occupying the territory in a systematic way, acting socially, politically, and economically in the shaping of the landscape; manipulating botanical species; domesticating animals; intervening on topography; and transforming the environment. According to Noelli (1993) and Assis (1996), the territorial organization of the Tupi-Guarani is constituted by the house (*oka*), where lies the nuclear family; by the village (*amundá* or *teýy*), where the extended family resides; by the set of villages included in a territory (*teko'á*); and by the set of *teko'á* that

configures a large territory as a nation (*guará*). By definition, *teko'á* constitutes a set of villages and camps (*tapyi*), interconnected by paths (*piabiru*). It configures a territory bordered by landforms such as rivers, hills, and streams. This territorial organization is defined by symbolic aspects and consolidated through political alliances that determine degrees of prestige and social status in relationships between villages (Fig. 4).

In the twenty-first century, Tupi-Guarani archaeology has adopted an Indigenous history approach, integrating and confronting archaeological, ethnohistorical, and ethnographic sources. There is also a concern with the observation of technology and behavioral patterns as a mechanism for understanding the archaeological record. In addition, there is a growing investment in political engagement, adding theoretical reasoning and scientific political agendas in defense of Indigenous heritage and civil rights as regards land reservations and the protection of environmentally threatened territories and heritage landscapes. In this sense, Tupi-Guarani

Tupi-Guarani Archaeology in Brazil, Fig. 4 Graphic idealization of a *teko'á*, showing the houses, traps, gardens, ports, jungle, and the pathways linking all the spaces (Modified from Assis 1996)

T

archaeology has overcome the old divide between strict archaeological and anthropological/linguistic perspectives, making it possible to approach the Tupi-Guarani people's history and culture in a holistic way.

Turkey: Archaeological Museums

Soner Ateşoğullari
General Directorate for Cultural Heritage and Museums, Ulus/Ankara, Turkey

Introduction

As archaeological material in Turkey is legally state property, archaeological museums have played a crucial role in state museum policies. In recent years, the Ministry of Culture and Tourism has been investing heavily in the establishment of museums associated with important archaeological sites. The construction program aims to present the excavation results using modern technology to enrich the visitor experience. New museums also engage in educational programs for their communities and include workshops and other facilities aimed at attracting children's attention and enhancing the value of the museums in their respective regions.

Key Issues/Current Debates/Future Directions/Examples

Museums of Turkey

The first museum in Turkey was founded in 1846 by Fethi Ahmet Pasha at Hagia Eirene, which had previously been used as a military depot in Istanbul. The museum was later renamed *Müze-i Hûmâyun* (Imperial Museum), and Mr. Edward Goold, who had been teaching at *Mekteb-i Sultânî*, was appointed director. *Asar-ı Atika Nizamnamesi*, the first thorough legislation regarding protection of ancient artifacts, was passed in 1869. The legislation required all parties to apply for permission from the Ministry of Education for excavations on Ottoman soil and banned overseas sales and movement of material while permitting local sales. In 1872, Dr. Philipp Anton Dethier was appointed director of *Müze-i Hûmâyun*. During his directorate, artifacts from the Hagia Eirene were moved to the

Tiled Kiosk Museum. In 1874, a second law was passed, which was proved unsatisfactory in fighting (abuse). A new age for Turkish museology began after Osman Hamdi Bey was appointed director of the museum. He played a pivotal role in the preparation of the new legislation for ancient artifacts, which forbade all transactions and export overseas. Istanbul Archaeological Museum, Konya Museum (1902), and Bursa Museum (1904) were also built during his directorate. He also played a crucial role in the first scientific excavations in Ottoman territory as well as in the formation of modern museological standards. Following his death, his brother Halil Edhem Bey took up on the role of director. He particularly focused on the development of museums in Anatolia. The Museum of Turkish and Islamic Arts (1914) and The Ancient Orient Museum (1925), both in Istanbul, were also established during his period (Fig. 1).

Istanbul Archaeological Museums consist of the Archaeological Museum, the Ancient Orient Museum (Eski Şark Eserleri Müzesi), and the Tiled Kiosk Museum (Çinili Köşk Müzesi). The museum complex was opened to visitors in 1891. They house a large number of finds from the Ottoman territory, material from Seljuk and Ottoman eras, and a Children's Museum (Fig. 2).

Turkey: Archaeological Museums, Fig. 1 Osman Hamdi Bey is one of the most prominent figures in the development of museums and archaeology in Turkey. (Public Domain)

After the War of Independence, Atatürk paid a great deal of attention to museums and personally contributed to the foundation of several. During the early years of the Republic, numerous museums were made accessible through development and restoration operations on a national scale. Besides construction of new museums, several architecturally significant buildings were converted to museums. Ayasofya (Hagia Sophia), built by the Roman emperor Justinian in 537, was designated as a monument museum in 1935. Another Justinian period church, Chora, was also arranged as a museum in 1945. Topkapı Palace, the seat of the administration from the time of Mehmet the Conqueror was converted to a museum by Atatürk's directive in 1924. The museum in Manisa, the core Lydian territory, was created in 1937 in a *madrasa* built by the famous sixteenth-century Ottoman architect Sinan (Fig. 3).

Ankara Ethnographic Museum, the first museum of the Republic, was opened to visitors in 1930 to display and house the cultural heritage of Anatolia beginning from the first Turkish states and principates to more recent times. Stemming from Atatürk's idea to establish a museum devoted to Hittite civilization, the growing number of Hittite objects brought to Ankara necessitated a large building. For this purpose, two Ottoman buildings were restored to establish the Museum of Anatolian Civilizations, which took its final form in 1968, one building having been reserved for the administrative section. The museum houses various objects from Paleolithic times to the Ottoman period, including many prominent examples from Çatalhöyük, the Assyrian Colonies, and the Phrygian, Lydian, and Urartian periods. In the core Hittite territory, namely, Çorum province, the first museum was established in 1940 in Alacahöyük, the site of the Early Bronze Age royal tombs and a Hittite town. The year 1968 saw the opening of two museums in the region, one in Boğazköy, where capital Hattusa is located, and in Çorum. In the Phrygian capital Gordion, a museum was built beside the so-called Tumulus of Midas in 1964. In Uşak, another Lydian territory, a museum was established in 1970. The repatriated pieces from

Turkey: Archaeological Museums, Fig. 2 Founded in late nineteenth century, Istanbul Archaeological Museums complex is still one of the most visited national museums. (Photo: Soner Ateşoğulları)

Turkey: Archaeological Museums, Fig. 3 The Museum of Anatolian Civilizations, stemming from Atatürk's idea to establish a museum devoted to Hittite archaeology, later developed into a museum presenting the whole ancient civilizations in Turkey. (Photo: Soner Ateşoğulları)

the so-called Croesus Treasure are displayed in the museum.

The museum directorate in Van Province in Eastern Anatolia, the central town of which covers the Urartian capital Tushpa, was established in 1972 for display after decades of collecting and storage of artifacts under state control. A considerable number of museum directorates established close to ancient cities in Muğla, Aydın, and İzmir provinces provide for effective management of the Aegean heritage in Western Anatolia. Those directorates are responsible for numerous open-air museums just as the Nevşehir and Ürgüp museum directorates in Cappadocia, where many rock-cut churches and underground settlements are found.

The Hellenic and Roman past of Anatolia is present in almost all the archaeological museums in Turkey, but museums in the coastal provinces in the Mediterranean, Aegean, Marmara, and western Black Sea regions are exceptionally rich in this material; examples include Antalya, Adana, Mersin, Hatay, İzmir, Bursa, Kocaeli, Sinop, and Samsun museums. Several inland provinces that

Turkey: Archaeological Museums, Fig. 4 Three-storied Gaziantep Zeugma Mosaic Museum presents the rich collection of mosaics and other finds from the riverside Roman city of Zeugma

have the ruins of prosperous ancient cities like Sagalassos (Burdur), Hierapolis (Denizli), Zeugma (Gaziantep), Pessinus (Eskişehir), and Perre (Adıyaman) also have equally remarkable collections.

The museums in southeastern Anatolia (Diyarbakır, Kahramanmaraş, Elazığ, Şanlıurfa, Malatya, Mardin, Gaziantep), the region comprising a remarkable part of Mesopotamia, house rich Neolithic and Chalcolithic finds brought from numerous excavations in mounds, some of which shed light on the beginning of agriculture and the domestication of animals.

As a result of the careful and meticulous work during 1970s and 1980s, there has been an increase in the number and variety of museums. An Act of 1983 (Number 2863) allowed private museums to be established. Today, there are a total number of 364 museums, 190 of which are under jurisdiction of the Ministry and 174 of which are private museums audited by it, among which are some that have won international awards like European Museum of the Year Award. In addition to these, there are 130 open-air museums under jurisdiction of the Ministry. An increasing number of new museums are no longer alienating and cold spaces, but are structures that host conferences, seminars, social and cultural events, exhibitions, publications for the education, and advancement of the public.

New Archaeological Museums

The momentum that has been generated in the past decade has allowed the Ministry to restore over fifty museums and recently to construct several new ones including Gaziantep Zeugma Mosaic Museum (Fig. 4), the world's biggest mosaic museum (2011), Kırşehir Kaman Kalehöyük Archaeology Museum (2009) (the design and construction expenses of which were covered by the Japanese government), Sivas Museum (2009), Eskişehir Eti Archaeology Museum (2011), Aydın Museum (2012), and Tokat Archaeology and Ethnography Museum (2012).

Turkey: Domestication

Camilla Speller
Department of Anthropology, University of British Columbia, Vancouver, BC, Canada

The turkey (*Meleagris gallopavo*) is a member of the order Galliformes, which include chickens, guineas, peafowls, and other terrestrial birds. Within the family Meleagrididae, there is one living genus, *Meleagris*, with two living species: *Meleagris gallopavo*, the North American turkey (or common turkey), and *M. ocellata*, the smaller bodied and more brightly plumed ocellated turkey.

Five wild turkey subspecies currently occupy distinct territories in North and Central America (Fig. 1) (Dickson 1992; Schorger 1966): *M. g. silvestris* (Eastern wild turkey) inhabits the deciduous forest and oak savanna of the eastern half of the USA, *M. g. osceola* (Florida wild turkey) resides in evergreen and tropical areas of southern Florida, *M. g. intermedia* (Rio Grande wild turkey) ranges over the south central plains and northeastern Mexico, *M. g. merriami* (Merriam's wild turkey) ranges within the montane woodlands of the Southwest USA, and *M. g. mexicana* (Gould's wild turkey) occupies the pine-oak forests of Southern Arizona and New Mexico, and northwestern Mexico. A sixth subspecies, *M. g. gallopavo* (South Mexican wild turkey), which occupied south-central Mexico, is now thought to be extinct (Dickson 1992). The closely related ocellated turkey currently occupies Mexico's Yucatan Peninsula and parts of northern Belize and Guatemala.

The turkey represents only vertebrate domesticated within ancient North and Central America and played an important spiritual and secular role in precontact indigenous cultures of Mesoamerica and the American Southwest. Although the origins and timing of turkey domestication are still unclear, researchers are continuing to expand our understanding of turkey husbandry and domestication using a range of zooarchaeological, biomolecular, and ethnographic approaches (Thornton 2016). Current archaeological and genetic evidence suggests that the Mesoamerican turkey was locally domesticated from *M. g. gallopavo* populations within south-central Mexico. Sporadic evidence of turkey use in the central Mexican highlands, coupled with the human-mediated spread of turkeys outside of their natural range into Oaxaca, the Gulf coast Olmec area, and into the Yucatan suggests that turkeys were under some degree of human control by the first half of the Preclassic or Formative period (1800 BCE–250 CE) (Thornton et al. 2012; Thornton and Emery 2015). Intensification of turkey husbandry seems to have begun in the Classic and Postclassic periods (600–1500 CE), and from historical accounts, it is clear that turkeys were raised in large numbers at many Mexican sites for both food and tribute to local leaders (Schorger 1966). In spite of its early introduction, common turkeys were not widely raised by the ancient Maya until the Postclassic period (1000–1519 CE); here, domesticated common turkeys are identified alongside the local ocellated turkey (*M. ocellata*), although it is unclear the degree to which the latter

Turkey: Domestication, Fig. 1 Assumed original distribution of the wild turkey subspecies in North America (Based on Schorger 1966)

was managed through captive rearing or breeding. Turkeys were widely distributed within Central America by Columbian times, reaching Peru in the late 1400s, Ecuador around CE 1587, and Chile around CE 1650 (Crawford 1992).

The Southwest domestic turkey seems to have a separate origin from the Mesoamerican turkey. Previous hypotheses assumed that initial domestication either took place in situ (with *M. g. merriami* as the progenitor) or in Mesoamerica with subsequent dispersal of domestic turkeys into the Southwest (following the general pattern of cultigens like maize, squash, and beans). However, ancient and modern DNA analyses suggest that either the Eastern or Rio Grande wild turkeys (*M. g. silvestris* or *intermedia*) represent the wild progenitor of the Southwest domestic turkey, with previously domesticated stocks being introduced into the region by 200 BCE (Speller et al. 2010).

The Ancestral Pueblo, the subsistence horticulturalists of the Colorado Plateau, were the predominant exploiters of turkey in the region. The first concrete archaeological evidence for domestic stocks in the Southwest begins c. 200 BCE–CE 500, with the recovery of turkey coprolites from the site of Turkey Pen Ruin, UT, indicating that turkeys were being confined and raised within a human habitation (Munro 2006). During the Basketmaker phases (100 BCE–CE 750), evidence for turkey exploitation and husbandry is restricted to some loose feathers, feather blankets, a few turkey bones, and some complete desiccated bird, indicating that turkeys were prized more for their feathers rather than for their meat (Munro 2006). After CE 900, there is intensification in turkey husbandry, evidenced by greater quantities of turkey bones, as well as higher frequencies of butchery marks, suggesting that turkeys were playing a more important role as a food source, especially in the Northern San Juan region (Driver 2002). This pattern continues until the sixteenth century when the effects of disease and conflict associated with Spanish colonialism, as well as the introduction of sheep and chicken, all contributed to dramatic declines in local turkey husbandry during the eighteenth and nineteenth centuries, perhaps even resulting in the complete extirpation of the Southwest domestic turkey.

Modern domestic turkey breeds worldwide seem to be descended from the Mesoamerican

domestic turkey and not the Southwest domestic breed. Turkeys were transported from Mexico to Europe in the early sixteenth century, where they quickly spread across the continent. Over the following centuries, several varieties were developed in Europe and subsequently imported to the US Atlantic Seaboard in the eighteenth century. Hybridizations between the European domesticates and the wild turkeys were widespread with heterosis producing much larger and more vigorous animals (Crawford 1992). These hybrid varieties eventually become the forerunner to the Narragansett, Slate, and Bronze turkeys of today (Marsden 1971). Most heritage breeds developed in Europe (e.g., Norfolk Black, Cambridgeshire Bronze, White Austrian, Buff, Blue, and Ronquieres) are smaller than North American wild turkeys, while those raised commercially for consumption (e.g., Broad-Breasted Bronze and Broad-Breasted White) tend to be larger (Marsden 1971). In general, turkeys raised for meat have white plumage; are top-heavy, with hypertrophied breasts and thighs; and reach sexual maturity faster than wild turkeys. Since the 1940s, turkeys have been under intense selection for weight, conformation, and an ability to be raised efficiently in confinement, resulting in an overall decline in reproductive abilities and fitness and a reduction in genetic variability.

U

Ubelaker, Douglas H.

Dawn M. Mulhern
Department of Anthropology, Fort Lewis College, Durango, CO, USA

Douglas H. Ubelaker is Curator in the Division of Physical Anthropology at the National Museum of Natural History, Smithsonian Institution in Washington DC. He received his B.A. with honors and his Ph.D. at the University of Kansas in 1968 and 1973, respectively. Dr. Ubelaker has served as a consultant in forensic anthropology to the FBI from 1978 to 2013 and has testified as an expert witness in numerous trials and hearings. Dr. Ubelaker has consulted in over 960 cases involving human skeletal remains since 1976. He holds the position of Adjunct Professorial Lecturer in the Department of Anatomy and the Department of Anthropology at The George Washington University in Washington DC and Adjunct Professor in the Department of Anthropology at Michigan State University in East Lansing, Michigan.

Dr. Ubelaker is a member of the American Academy of Forensic Sciences (AAFS) and became a Fellow of the Academy in the Physical Anthropology Division in 1987. He has served as President of the Academy two times, from 1995–1998 and 2010–2012. Dr. Ubelaker became a diplomate of the American Board of Forensic Anthropology in 1979. He established the AAFS Humanitarian and Human Rights Resource Center in 2015 and currently serves as its Chair. He is a member of the American Association of Physical Anthropologists, The Paleopathology Association, The Society of American Archaeology, Sigma Xi, the International Academy of Legal Medicine in the Forensic Anthropology Society of Europe Section and is a Fellow of the American Association for the Advancement of Science and the Washington Academy of Sciences. Dr. Ubelaker is also a member of the Ellis R. Kerley Forensic Sciences Foundation Board of Directors.

Dr. Ubelaker has published extensively in skeletal biology, with hundreds of publications since 1966, particularly in the areas of New World bioarchaeology and methods and techniques in forensic anthropology. He has served on the editorial boards of many publications including the Journal of Forensic Sciences, Forensic Science Communications, Homo: Journal of Comparative Human Biology, Anthropologie: International Journal of the Science of Man, Human Evolution, the International Journal of Anthropology, Global Bioethics, and Revista Española de Antropología Física.

Dr. Ubelaker has received numerus national and international honors; he was the recipient of the Memorial Medal of Dr. Ales Hrdlicka, Humpolec, Czech Republic in 1999, the Anthropology Award of the Washington Academy of Sciences in 2000, the T. Dale Stewart Award by the Physical Anthropology Section of the

American Academy of Forensic Sciences in 2001, the FBI Director's Award for Exceptional Public Service in 2002, the Federal Highway Administration Pennsylvania Division Historic Preservation Excellence Award in 2003, a special recognition award by the FBI in 2004, he was elected Miembro Honorario of the Sociedad de Odontoestomatólogos Forenses Ibero Americanos in 2009, he was the recipient of the Hong Kong Forensic Foundation Award in 2014 and was elected Doctor (Honoris Causa) by the University of Cordoba, Argentina in 2015.

Ucko, Peter (Cultural Heritage Management)

Siân Jones
Archaeology, School of Arts Languages and Cultures, University of Manchester, Manchester, UK

Basic Biographical Information

Peter John Ucko was one of the most influential archaeologists of his generation. He played a decisive role in the transformation of the discipline and the recognition that the past is profoundly political. During his career he challenged the way we understand and engage with cultural heritage, raising fundamental questions about ownership, identity, authenticity, and the role of the past in the present. He is perhaps most widely known for his role in the creation and development of the World Archaeological Congress, but the antipathy to racism and social injustice that informed this was an important strand throughout his entire career.

Peter was born in 1938 to intellectual Jewish emigrants from Germany. He was educated at Bryanston School in Dorset and North West London Polytechnic, before taking a degree in anthropology at University College London (1956–1959). He had been fascinated by Egyptian artifacts as a boy and took courses with a strong archaeological bias, subsequently staying on to complete a Ph.D. on Egyptian figurines in 1962. For the next 10 years he remained at UCL lecturing in anthropology. During this phase in his career, Peter's research focused on material culture studies, and he produced a number of brilliant and original pieces of work, including a comparative study of penis sheaths and his work on Paleolithic cave art with his then partner, Andrée Rosenfeld. Peter's intense, thorough, and questioning stance was already apparent, and he developed a profound understanding of cultural diversity. His legendary organizational and editorial talents were also evident in the two influential conferences he organized and published, *The Domestication and Exploitation of Plants and Animals* and *Man, Settlement and Urbanism*. However, it was his subsequent experience in Australia that crystallized a strong interest in the role of archaeology and anthropology in wider society.

Major Accomplishments

In 1972, Peter was appointed Principal of the Australian Institute of Aboriginal Studies, which proved an important radicalizing moment in his life. On arrival he found the institute was dominated by White people and preoccupied almost

entirely with recording the remnants of what was then perceived as a dying "race." Recognizing that the situation was untenable, Peter responded to increasing Aboriginal activism by transforming the internal structures of the institute and bringing in Aboriginal representatives. He also refocused its research culture on contemporary practical and political issues, in particular Aboriginal land claims. Today such matters might seem self-evident, but in the 1970s they marked the start of a seismic shift in the power relations between indigenous people and the predominantly White scholars who studied them (Ucko 1983). For Peter personally, the experience was to have a profound impact leading to a lifelong concern with the archaeology of indigenous societies and the impact of neocolonial relationships on the conservation, management, and interpretation of cultural heritage (Figs. 1 and 2).

In 1981, Peter returned to England with the anthropologist Jane Hubert, who became his long-term partner. She was an important influence on his subsequent career and a source of unswerving support in face of subsequent challenges. Peter was appointed Professor of Archaeology at the University of Southampton, but while waiting to take up the post, he worked briefly as a consultant on heritage to the newly independent government of Zimbabwe. There he proposed community-led "culture houses" that would be at the heart of community life (Ucko 1994), as an alternative to European-style museums. That same year, he was also asked to organize and host the 11th Congress of the International Union of Pre- and Protohistoric Sciences at the University of Southampton, which was scheduled for 1986. After some deliberation, he accepted, recognizing that it provided an opportunity to further a comparative and genuinely world archaeology that would include scholars from developing countries and indigenous peoples (Ucko 1987). With characteristic energy and determination, he set about realizing this vision, only to find the whole endeavor threatened by the growing crisis surrounding the South African apartheid regime. By 1984, it became clear that there was growing pressure for an academic boycott of South African scholars in protest at the racist policies of the apartheid government. Furthermore, if the South Africans attended, many of the organizations and individuals whom Peter had worked so hard to include would withdraw from the congress. Under immense pressure and with staunch support from Jane, Peter eventually decided to exclude the South Africans, leading to international outcry over the principle of academic freedom that would split the archaeological world for some time. The International Union withdrew its recognition and support, but a new committee was formed in early 1986 and the first World Archaeological Congress (WAC) took place later that year.

Ucko, Peter (Cultural Heritage Management), Fig. 1 Peter as Principal of The Australian Institute of Aboriginal Studies in the early 1970s. (Photo: Jane Hubert)

The congress was an enormous success with over 1,000 delegates from around the world, including indigenous speakers. It also marked a turning point in the history of archaeology, in the form of what Stephen Shennan (2007) called a very public loss of political innocence. The publications that ensued under the *One World Archaeology Series* represented a phenomenal

Ucko, Peter (Cultural Heritage Management), Fig. 2 Peter with Alex Okpoko and Thurstan Shaw in Nigeria in 1989. (Photo: Jane Hubert)

achievement (Wheatcroft 2007). Subject to Peter's keen editorial eye, as overarching Series Editor, they are a lasting testament to his vision of a comparative, inclusive, and politically engaged world archaeology. Among the many thematic titles, there are several that pertain to cultural heritage and which became seminal works. While not disregarding the work of individual editors and contributors, these works are ultimately a product of Peter's energy and foresight (e.g., Layton 1989a, b; Shennan 1989; Gathercole and Lowenthal 1990; Stone and Mackenzie 1990).

Peter remained committed to this vision for the rest of his academic career, leading the way with many new and often controversial developments in the realm of public archaeology and heritage. One area of note from the late 1980s onwards was his concern with the treatment of the dead, an issue of particular concern to many indigenous peoples. Here Peter collaborated very closely with Jane Hubert while also promoting doctoral and postdoctoral research on human remains collections. In 1989, WAC adopted the Vermillion Accord at an Inter-Congress in South Dakota, USA, making it the first organization to recognize the rights of local communities, descendants, or guardians alongside respect for scientific research in relation to human remains. Other areas that benefitted from Peter's penetrating questions and characteristic tenacity include archaeology and education; the archaeology of ethnicity; the history of the discipline, heritage legislation, and management; the treatment of sacred sites and places; the presentation of the past; and more broadly the sphere of public archaeology.

In 1996, Peter was appointed Director of the Institute of Archaeology at University College London. He set about transforming it into a leading international center of excellence in archaeology and inserted the contemporary significance of the past into almost every corner of the institution. New programs in cultural heritage and public archaeology were launched, and along with Neal Ascherson, Peter initiated the first journal dedicated to the ethics and politics of the profession, *Public Archaeology*. He returned to his early interest in Egyptian archaeology, acting as series editor for an eight-volume set, *Encounters With Ancient Egypt*, which included his own volume focusing on how Egyptian heritage has been represented and valued (Ucko and Champion 2003; also Ucko and Quirke 2006). He also built new international arenas of collaboration, particularly with the School of Archaeology and Museology at Peking University, and a joint *International Centre for Chinese Heritage and Archaeology* was founded. During this period, Peter also found time to return to his own research, publishing on a wide range of topics mostly in the realm of cultural heritage and

public archaeology. The same themes can be found including indigenous archaeology, repatriation, museum collections, the role of heritage in constructing ethnicity, and ethics of tourist presentations (e.g., Ucko 1998, 2000, 2001; Ucko and Layton 1999; Ucko et al. 2006).

Following his retirement in 2005, the Institute of Archaeology, in collaboration with WAC, organized a conference and edited book inspired by his work, both fittingly titled *A Future for Archaeology: the Past in the Present* (Layton et al. 2006). His untimely death in 2007 was an enormous loss to the discipline and the many people whose lives he had touched throughout his career. His legacy is the realization of his vision of archaeology as a discipline that is socially and politically engaged and in which archaeological heritage management is just one aspect of an all-encompassing public archaeology. Aside from his own research, he inspired and mobilized others, fashioned enormously ambitious and successful conferences and book series, and restructured the discipline of archaeology to make it more accessible to non-professionals with an interest in the past, particularly indigenous peoples. Very few would have had the force of personality, charisma, insight, and energy necessary to bring about such a lasting transformation.

Ucko, Peter (Indigenous Archaeology)

Peter Stone
International Centre for Cultural and Heritage Studies, Newcastle University, Newcastle upon Tyne, UK

Basic Biographical Information

Peter Ucko (1938–2007) was one of the most influential archaeologists of the second half of the twentieth century. He rejected the claim that

archaeology was an "objective science" and emphasized its subjective, frequently political; nature, stressing the central role of those affected by the past and in particular indigenous peoples.

A childhood fascination with Egyptology led Peter Ucko to undergraduate study in anthropology (the only way he could study Egyptology) in London followed by a Ph.D. on prehistoric figurines at the Institute of Archaeology. In 1962 he returned to the UCL anthropology department to teach material culture and later a course on "Primitive Art" that was the basis of the seminal *Paleolithic Cave Art* (Ucko and Rosenfeld 1967). Ucko's move from Egyptology, to anthropology, to the Institute, and back to anthropology foreshadowed his lifelong multidisciplinary approach to the study of the past, as one inextricably mixed-up with an understanding of the present.

Major Accomplishments

The discrepancies between the incomplete and unclear figures represented in the actual Paleolithic art in French caves and the very clear, precise reconstructions of the same art published by Breuil, led Ucko to carry out his own project – at the Spanish cave of Hornos de la Peña (1971–1973). Ucko found the lack of knowledge of the cultural context of Paleolithic art incredibly frustrating, and he began to study more recent hunter-gatherer rock art. This led him to accept the post of Principal of the Institute of Aboriginal Studies in Australia, an appointment that was a major catalyst for a change in the way archaeologists and anthropologists studied Aboriginal society. When Ucko arrived the Institute was a totally white, semigovernmental organization tasked with recording the languages and customs of Aboriginal people before they became extinct. However, Ucko was quickly confronted by active Aboriginal communities who had very strong views on the interpretation by western-trained "objective" scientists of the art that was still very much part of their social structure. Ucko left Australia after nearly a decade of working with Aboriginal people over the interpretation, management, and control of their art and, more fundamentally, of their past, and their present and future role in Australian society. That he was succeeded by an Aboriginal as Principal is a testimony to the astonishing change overseen by Ucko.

Ucko returned to the UK via the newly independent Zimbabwe where he was asked to advise the government on the reorganization of the museum service. Ucko's report recommended the development of 56 culture houses – an approach he had seen in practice in Papua New Guinea – effectively returning the heritage to the control of local communities. This was rejected and the colonial system of five regional museums retained: while unstated, the potentially unifying ideal of a homogeneous past presented through a group of nationally controlled museums was far preferable to the new government to the decentralizing of interpretation and loss of control to local communities.

In 1981 Ucko became Professor of Archaeology at the University of Southampton. He immediately instigated a revision of the traditional archaeological curriculum – introducing anthropology and sending key staff on sabbaticals to the USA, Australia, and the Cameroon. He also headed a national review of archaeology at university that advocated focussing teaching at a few big departments that could offer the wide-ranging world archaeology that he saw as the basis of a valid and stimulating study of the past that was of relevance to the present and future. As in Zimbabwe, his plan was rejected but had instigated a debate concerning the content and role of archaeology that continues to resonate. In accepting that archaeology at university would be the preserve of a tiny percentage of the population and noting the increasingly inward looking school history curriculum of the Thatcher government, Ucko also created a small team to provide support, and to develop educational resources, for teachers.

It was while at Southampton that the above strands came together in Ucko's greatest contribution to the discipline: the creation of the World Archaeological Congress (WAC). Ucko originally declined the invitation to organize the 11th

congress of UNESCO's International Union of Prehistoric and Protohistoric Sciences (IUSPP) but eventually agreed on the condition that anyone with a legitimate interest in the past, and not just academic scholars, would be allowed to participate and that funding would be found to enable those from poorer parts of the world to attend. Ucko planned a meeting that was to be academically robust and socially relevant. However, it was a meeting not without controversy as wider political events conspired to demand that WAC either allow colleagues from South Africa to participate or lose the contributions of many others from around the world who would refuse to attend if South Africans were present. It was an astonishingly difficult decision, but the overt and extreme manipulation of the past within schools to serve the political ends of a tiny white majority, coupled with the almost complete lack of access to education for the majority, set within the wider extremes of the abhorrent apartheid regime compelled the organizers, led by Ucko, to ban South African participation. This one act of exclusion opened discussion of the archaeological past to disparate groups from all over the world in an unprecedented way. At the end of the 1986 Congress, participants demanded that the organizers either come to reconciliation with IUSPP or create a new world organization. Reconciliation was impossible as IUSPP clung to an ideal of academic freedom, and Ucko turned his efforts from organizing a one-off conference to the creation of a world organization. It was little surprise that the next meeting of WAC focussed on the archaeological treatment of human remains nor that it was organized by archaeologists in cooperation with the elders at the Indian reservation at Wounded Knee.

In 1996 Ucko became Director of the Institute of Archaeology in London. He once again immediately set about a review of the curriculum and, with significantly more resources than had been available in Southampton, set about making the Institute an international hub of archaeology. He retired in 2005 and was still working on a variety of projects, including a major collaboration with China, on his untimely death in 2007.

Uhle, Friedrich Max

Elmo Leon
National Museum of Archaeology, Anthropology and History of Peru, Lima, Peru

Basic Biographical Information

Friedrich Max Uhle (1856–1944) (Fig. 1) was born on March 23, 1856, in Dresden (Sachsen) in Northern Germany. Because of his pioneer huge contribution to the Andean archaeology, he is considered by some archaeologists as the "father of the Peruvian archaeology (Hoeflein 2002; Kaulicke 1998)."

After his dissertation in linguistic in Leipzig, he met for the very first time Peru when working

Uhle, Friedrich Max, Fig. 1 Max Uhle (Photo: Ibero-Amerikanisches Institut – Preußischer Kulturbesitz, with permission)

as an assistant in the Royal Museum of Zoology, Anthropology, and Ethnography of Dresden. Next he moved to Berlin and therefore was able to study and examine the recent excavated remains from Ancón by Wilhelm Reiss and Alphons Stübel. This last scholar and the eminent ethnologist Adolph Bastian supported Uhle's endeavor to travel to the Andes.

Uhle arrived in South America in 1892 and 3 years later was hired by the University of California to form a collection of ancient Peruvian remains. In 1896 he traveled to Lima to gather archaeological remains from Ancón and the following year conducted excavations in the Pachacamac Ruins. The final report of this field research published in 1903 is considered by a number of archaeologists the very first scientific archaeological report in the history of Peru, especially because of its brilliant stratigraphical and contextual lessons, virtual basic notions ever in archaeology. Uhle's archaeological scientific pioneer contribution was previously recognized by his book on the Tiwanaku culture in Bolivia (1892).

On the rise of the twentieth century, Uhle undertook surveys in a number of valleys of the central and northern coast of Peru. Some years later, he conducted fieldwork in the Peruvian Highland. By that time span, he became director of the Museum of Archaeology of Peru. Between 1911 and 1919, he addressed to the Chilean archaeology publishing seminal papers on the archaeology of this country. Uhle also gathered archaeological remains to form the National Museum of Ethnology and Anthropology. Further, upon invitation of Jijón y Caamaño, he went to Ecuador where he also conducted excavations and surveys until 1932 discovering new cultures and contributing to the Andean past.

In 1933 he came back to Germany and held lessons as professor at the University of Berlin. Max Uhle finally in 1944 passed away in Loben, Alemania, muy cerca de la frontera con Polonia (Rowe 1954).

Major Accomplishments

Max Uhle contributed as a pioneer in Andean archaeology. Among his most transcendental contributions, we can mention:

Proposing and establishing the very earliest chronological frame to the Andean pre-Columbian times

Applying the basic principles of modern archaeology, namely, stratigraphy and contexts, in the Andean archaeology

Introducing the "Horizon concept" in the Andean archaeology to fusion similar cultural traits throughout the Andes

Publishing the very first complete archaeological reports based on his excavations in key *gisements* of the Andes, Pachacamac, and Tiwanaku

Applying a vast interdisciplinary study in his archaeological researches including geology, relative chronology, paleoclimate, ethnology, linguistic, and even archaeoastronomy

Assessing within a real concept some key past activities of the Andean people as ritual graves and "beyond dead" (this also implies the relevant importance of sanctuaries in the past Andes)
Promoting preservation and defense of the Andean archaeological heritage

uKhahlamba-Drakensberg Park (South Africa), Rock Art at

Ndukuyakhe Ndlovu
Department of Anthropology and Archaeology, University of Pretoria Hatfield, Pretoria, South Africa

Introduction

The study of rock art in southern Africa dates back to the early eighteenth century when rock art was first "discovered" and reported by early travellers (Mitchell 2002; Rust 2008). The Portuguese are credited with having made this first "discovery" in what was then known as the Portuguese East Africa (then a Portuguese colony and now Mozambique). It took another three decades before the same "discovery" could be repeated along the Fish River by an exploratory expedition under the leadership of Ensign August Frederic Beutler (Bahn 1998). These early "discoveries" were viewed within the political lenses of the time which put the "natives" at the bottom end of the human scale (see Anderson 1888, 1907; Arbousset and Daumas 1846; Bryant 1929; Dart 1925; Ellenberger 1912; Ergates 1905; Evans 1911; Fry 1910; Howard 1910; Moodie 1855; Moszeik 1910; Orpen 1874; Stanford 1910; Stow 1905). Since these early "discoveries," we have come to learn a lot about the identity of the authors behind this rock art and the reasons behind their existence. In this entry, I discuss rock art from the uKhahlamba Drakensberg Park (Fig. 1). I begin by offering a broad background before discussing rock art from this region in details. I conclude the entry by presenting some of the areas where visitors can have an opportunity to see these aesthetically pleasing images within the uKhahlamba Drakensberg Park.

Background

The uKhahlamba Drakensberg is the highest mountain range in southern Africa, rising to about 3000 m or more in places (Dodds 1975). uKhahlamba Drakensberg Park covers a land mass of about 242,813 ha. This landscape is characterized by majestic mountains with rock art that makes it the richly painted area south of the Sahara desert. Furthermore, uKhahlamba Drakensberg Park is one of the areas with the highest density of prehistoric rock art in the world, with an estimated 40,000 individual images in over 600 known sites, making up 35% of all of South Africa's San rock art sites (Derwent et al. 2001). This mountain range, the highest south of Kilimanjaro, is among the comprehensively researched areas in Southern Africa (Willcox 1956, 1963a, b, 1976, 1984; Rudner and Rudner 1970; Pager 1975; Lewis-Williams 1974; Vinnicombe 1976; Wright and Mazel 2007). Research over the years has shown that

uKhahlamba-Drakensberg Park (South Africa), Rock Art at, Fig. 1 The location of uKhahlamba Drakensberg Park (indicated with a star) within the KwaZulu-Natal Province. The dots indicate the general extend of the Drakensberg mountains

Bushmen were authors of the paintings in the uKhahlamba Drakensberg Park. Estimations are that they began making this rock art in the uKhahlamba Drakensberg Park as early as 3000 BP, continuing until the twentieth century (Vinnicombe 1976; Mazel and Watchman 2003; Wright and Mazel 2007; Mazel 1982, 2009a, b). Archaeological evidence has suggested that hunter-gatherers began occupying the uKhahlamba Drakensberg Park around 5000 years ago (Mazel 1984, 1989, 2011). Many interpretations of this art have been provided over the years, largely informed by outsiders view on this rock art tradition. Particularly in the past five decades, research has shown that these paintings do not necessarily represent the daily life of Bushmen; instead, they reflect the complex spiritual life of the Bushmen (see Vinnicombe 1976; Lewis-Williams 1977, 1981, 1983, 1990; Pearse 1989; Deacon and Deacon 1999; Mguni 2002).

uKhahlamba Drakensberg Park was the second site to be accorded the universal status of significance, getting inscribed into the World Heritage List. The uKhahlamba Drakensberg Park was inscribed into the World Heritage Site list partly because of its well-known rock art. This followed South Africa's ratification of the World Heritage Convention in 1997 following the formal end of apartheid. It was during the 24th session of the United Nations Educational, Scientific and Cultural Organization (UNESCO) World Heritage Committee on 29 November 2000 at Cairns in Australia that the uKhahlamba Drakensberg Park was so recognized for its natural and cultural

values (Derwent et al. 2001; Wright and Mazel 2007). The inscription was made under cultural criteria (i, iii) and natural criteria (vii, x), thus becoming the 23rd mixed World Heritage Site. Notably, the area proposed for inscription excluded the communally owned land to the north. The un-inscribed portion of the uKhahlamba Drakensberg Park is an area belonging to the amaNgwane and amaZizi Traditional Councils. This area lies between the northern and southern sections of the Park. The nomination of uKhahlamba Drakensberg Park was in line with the goals to rejuvenate the economy as set by the South African government in the White Paper on tourism gazetted in 1996. Therefore, having sites declared as World Heritage Sites was seen as an investment towards achieving that aspiration (Ndlovu 2005).

Since this inscription approved in 2000, the boundary of the World Heritage Site has since been amended. This decision was made during the 37th session held from 16–27 June 2013 at Phnom Penh in Cambodia. As a result, Sehlabathebe National Park in Lesotho has now been added to the uKhahlamba Drakensberg Park on the basis of criteria (i), (iii), (vii), and (x). The new, enlarged World Heritage Site is now known as Maloti-Drakensberg Park, Lesotho/South Africa.

Rock Art in the uKhahlamba Drakensberg Park

There is a significant variety in the motifs painted within the uKhahlamba Drakensberg Park. As in other parts of South Africa, there is a significant dominance of human figures followed by animal representations. For example, Vinnicombe (1976) recorded 150 sites in the southern uKhahlamba Drakensberg Park and surrounding areas where she identified 8478 paintings, of which 3606 were paintings of animals. Based on faunal analysis, it has been argued that the choices of animals in rock art has no relationship with their significance for subsistence purposes. Instead, animal representation relates more closely to Bushmen social practice and religious beliefs (Lewis-Williams 1972, 1974, 1981; Vinnicombe 1976; Chaloupka 1984; Flood 1989; Kinsey 1989; Waite 1989: 339; Mazel 1989; Lenssen-Erz 1994: 276; Rice and Paterson 1996; Deacon and Deacon 1999).

Representation of Human Figures

Human figures dominate in the uKhahlamba Drakensberg rock art. It is male figures that are best represented compared to women, who are easily identifiable by typical female features. These human figures are represented in a variety of scenes, involved in different activities from battle, hunting, to ritual events.

The context in which human figures are represented in hunting scenes once promoted a view that rock art was made as part of the so-called hunting magic. It was mainly through rock art conducted by Pager (1971, 1975) in the Didima Gorge that this theoretical interpretation was disproved. Didima Gorge has 17 recorded rock art shelters, composed of about 3909 paintings. Of these paintings, only 29 are hunting scenes. Their almost absence in rock art clearly challenges the thinking that people painted themselves in hunting scenes with the hope of being successful in a real hunt.

Besides hunting scenes, human elements have also been incorporated into representations commonly known as therianthropes. These are motifs that combine human and nonhuman features (Jolly 2002: 85). According to Jolly (2002: 86), "Antelope heads, torsos, legs, hooves, tails and postures may all be combined in different ways with humanheads, torsos, limbs, hands, feet and postures." There are also the so-called winged therianthropes, which have also been termed flying buck. As mentioned by Jolly (2002: 86), these types of therianthropes have "wing-like appendages or hold their arms in a wing-like position. These usually combine antelope features with those of humans and birds" (see also Lee and Woodhouse 1964; Pager 1971, 1975; Lewis-Williams 1981, 2003). The idea behind therianthropes is that when shamans went into trance, they got transformed. Generally, these motifs are not widely represented in

South African rock art. For example, of all the paintings recorded by Pager (1971) in Didima Gorge, only 4% were representative of therianthropes. The same percentage was recorded by Lewis-Williams (1981) in Barkly East. Vinnicombe (1976) recorded only 3% of therianthropes in her research study in the uKhahlamba Drakensberg.

uKhahlamba Drakensberg rock art has also been defined by a number of human figures involved in raiding scenes. This rock art was most probably produced during the contact period, during which other groups (African farmers about 2000 years ago, Voortrekkers in 1837, and the English in 1845) came to reside in the uKhahlamba Drakensberg (Pager 1971; Liebenberg 1972; Willcox 1976; Guest 1978; Wright and Mason 1983: 29; Willcox 1984: 9; Pearse 1989; Anderson and Wahl 1998). It has been argued that these arriving new communities significantly increased the competition for resources, thus impacting on the livelihood of Bushmen groups in the area. This saw the beginning of cattle and horse raiding conducted by the Bushmen in order to survive (Liebenberg 1972: 16; Willcox 1976, 1984; Anderson and Wahl 1998; Spencer 1999; Speirs 1999). The raiding worsened between 1840 and 1872 (Ergates 1905; Wright 1971; Vinnicombe 1976; Dowson 1995). During this period, there were three periods of raids: 1845–1852, 1856–1860, and 1868–1872 (Wright 1971; Mazel 1981). Bushmen were confronted with violent scenes (Campbell 1986). Evidence from the Southern uKhahlamba Drakensberg, for example, shows rock paintings depicting European and Nguni-speaking settlers on horseback and scenes of cattle raiding (Vinnicombe 1976; Johnson 1960; Campbell 1986; Lewis-Williams and Dowson 1989; Dowson 1994; Challis 2008, 2009, 2012). It can be very easy to read these rock art images historically. However, rock art researchers have argued that there was a deeper meaning behind these paintings rather than them being reservoirs of historical events in the areas where they were represented (see Hampson 2014). According to Hampson (2014), the depiction of Europeans and other agriculturalists should be interpreted as Bushmen negotiating power with these settles in the spirit world.

Animal Representation

There are a number of animal species represented in the uKhahlamba Drakensberg. Among these animals, eland are quantitatively the most dominant. There are over 2000 painted eland within the uKhahlamba Drakensberg Park. This quantitive dominance is followed by about 1000 painted rhebuck (Mazel's uKhahlamba Drakensberg Park rock art recording project from 1979 to 1981). As can be deduced, eland have about 50% numerical dominance over the second most painted animal species. This illustrates the significant dominance eland has in rock art from this region. This dominance is not consistent. The paintings of rhebuck at the Royal Natal Nature Reserve (RNNR) in the northern uKhahlamba Drakensberg Park outnumber those of eland. The numerical difference between the two animal species is relatively small. This is the only place in the uKhahlamba Drakensberg Park where rhebuck outnumber eland paintings. Moving southwards of the uKhahlamba Drakensberg Park, eland begin to take dominance over not only rhebuck but other painted animal species. Even when their percentage drops (e.g., Mkhomazana, Cobham) in certain areas moving southwards, they are still far dominant over other animal species.

It is not only eland and rhebuck that are characterized by an uneven distribution within the rock art of the uKhahlamba Drakensberg Park. For instance, there are more baboons at the Cathedral Peak Nature Reserve (CPNR), more snakes at Giants Castle Nature Reserve (GCNR), more hartebeest and elephants at Cathedral Peak and uMkhomazana, respectively, than anywhere in the uDP. These animals, baboons, snakes, hartebeest, and elephants, do not outnumber eland where they are painted. As indicated earlier, it is only the rhebuck THAT does so in the north, at the RNNP. Horses are significantly dominant in the southern regions of uKhahlamba Drakensberg Park as opposed to cattle which dominate in the northern portions (see Vinnicombe 1976).

Composition of Paint

Southern African rock art is generally defined by the use of a variety of colors, all of which came from naturally occurring pigments that were mined in the vicinity of painted landscapes. The same is applicable in the uKhahlamba Drakensberg Park. Most of the paintings are red, a colour that came from red ochre. Other colors used were yellow, black, orange, and white. Ochre, charcoal, and manganese, from which these colors largely originated from, was grounded into powder, then mixed with binders such as animal blood, fat, beeswax, egg white, water, and plant sap. White pigment, which fades away much quicker, was made from clays or animal droppings while black came from charcoal and manganese oxide. Besides these general colors, Bushmen were also able to produce a variety of other colors from mixing these different primary pigments. A large variety of such colors were generally used in the shaded polychromes. Brushes were made from different bird feathers or from animal hair.

As it is customary with other artistically produced works, the initial idea with rock art was that its production developed from simple, monochrome paintings to aesthetically pleasing polychrome paintings (see Solomon 2011). This viewpoint is no longer well supported.

Dating of Rock Art

In general, there has not been many attempts to date southern African rock art. The same is applicable in the uKhahlamba Drakensberg Park. The earliest actual dates for uKhahlamba Drakensberg Park paintings derives from a bichrome eland at Main Caves North, in the central uKhahlamba Drakensberg Park, where the associated crust has been dated to 2900 and 2760 years ago (Mazel and Watchman 1997, 2003; Mazel 1996a, b, 2009a, b). It is, therefore, possible that painting emerged here between 2500 and 3000 years ago, or perhaps earlier, and that this phenomenon is related to the intensification of hunter-gatherer occupation of the northern uKhahlamba Drakensberg Park. Other dating techniques that have been applied in the uKhahlamba Drakensberg Park rock art include the Harris Matrix (Russell 1997, 2000; see also Chippindale and Taçon 1993). This technique became important particularly in the absence of detailed chronologies created based on direct dating (Swart 2004). While acknowledging its potential significance in the rock art of uKhahlamba Drakensberg Park, this methodological approach has been criticized by Pearce (2002, 2006, 2010), resulting in an exchange between him and the proponents of this technique (Swart 2006; Russell 2012).

As Bonneau et al. (2017a: 659) notes, it has been difficult to create rock art chronologies chronologies "because of the frequent lack of datable material and the difficulty of removing contamination from samples." This challenge is not just applicable to the uKhahlamba Drakensberg Park, but it extends to other regions within southern Africa and beyond. With recent technological advancements, it seems there might be hope for the challenge of creating rock art chronologies from direct dating to be addressed (see also Bonneau et al. 2011, 2012, 2017b; Pearce and Bonneau 2018).

Presentation of Rock Art

To "tap" into the tourism market resulting from the designation of various portions of the uKhahlamba Drakensberg Park as nature reserves and the inscription of this area on the list of World Heritage Sites, rock art centers have been constructed. The aim has been to create areas where rock art can best be presented to the public (Duval and Smith 2012). There are two rock art centers in the uKhahlamba Drakensberg Park (Ndlovu 2012). One in the Kamberg Nature Reserve and the second one at Cathedral Peak Nature Reserve. The former was officially opened in 2002 and visitors can access an audiovisual facility where they watch a documentary on rock art of the area. They are also generally introduced to Game Pass Shelter which can be visited afterwards. The latter has a rock art center named after

the famous Didima Gorge. This center has a museum and an entertaining rock art documentary which addresses the ritual significance of rock art in general. Visitors have an opportunity of visiting few rock art sites in the vicinity of this rock art center but cannot officially be taken to Didima Gorge because it is considered inappropriate for management purposes. Besides these two centers, there are a number of rock art sites throughout the uKhahlamba Drakensberg Park that can be visited by tourists.

Underwater Archaeology

Colin J. M. Martin
University of St Andrews, St Andrews, Scotland, UK

Introduction

Some archaeological features lie under water, either because they were deposited there by accident (e.g., shipwrecks) or design (e.g., votive offerings), or because the ground in which they were originally preserved subsequently became inundated by rising water levels, subsidence, coastal erosion, seismic events, or human agency. The mere fact of submergence, however, does not of itself define the investigative disciplines applied to their study. Sunken cities, for example, are the preserve of investigators familiar with the principles of urban archaeology, who must relate their findings to a wider corpus of studies in this field irrespective of whether they were conducted above or below the water. Isolated finds of prehistoric material brought up from the seabed by trawling or dredging, and the survival of fragments of the now-submerged landscapes that

contained them, demand the attention of prehistorians and geomorphologists familiar with the wider contexts to which such evidence relates and can apply the appropriate techniques and resources to their analyses.

The fact that archaeological evidence may be found under water is not directly relevant to its interpretation, other than perhaps as a factor in its survival. "Underwater Archaeology" is thus a potentially misleading term, for it is no more than the descriptor of an environment in which a variety of archaeological work may be conducted. We do not speak of "desert" or "jungle" archaeology but categorize studies by period, region, or theme (e.g., "Iron Age"; "Polynesian" or "nautical").

Definition

This said, some archaeological themes often involve a significant amount of underwater work. These may include:

Maritime archaeology, which is the interpretation through surviving physical evidence of any activity associated with humankind's past relationship with the sea. Most obviously, it includes the investigation of seagoing ships, boats, and other floating craft, whether as surviving vessels, boat-burials, abandoned hulls, ship components and fittings, or sunken wrecks. It also deals with the purpose, operation, and management of watercraft, the technicalities of their construction, and their characteristics as self-contained social, economic, and political entities which in some (though not necessarily all) ways may be representative of their parent cultures ashore. More broadly, maritime archaeology is concerned with the wider infrastructures of human activities associated with the maritime environment, many of which may be situated wholly or partially on land. Such aspects might include harbors; shipbuilding and related resource extraction; shore structures associated with seagoing activities; navigational aids; exploration; cargoes and trade; predation (fishing and piracy); the projection of power and status; warfare; ritual; and recreation. Maritime topics frequently interface with what might be regarded as more overtly terrestrial activities but attempts to characterize such buffering zones (of which the coast itself is the most obvious) as hard lines of separation are illogical and self-defeating. It is connection and interaction across the interfaces that we seek, not the arbitrary setting of boundaries.

Nautical archaeology is the specialized study of ships, boats, and other past floating craft by examining their surviving remains. It includes freshwater as well as seagoing vessels. Documentary research, iconography, ethnology, and experimental techniques are often combined with archaeology in pursuing such studies.

Submerged-site archaeology is the investigation of any archaeological feature or structure once on land but now wholly or partly covered by water. It may include the study of submerged former landscapes and sunken habitation sites such as inundated cities or lake dwellings. Riverine or lacustrine sites such as the foundations of bridges and other structures built under water may also be included in this category, as may lost items, rubbish, or votive objects deposited in lakes, rivers, wells or *cenotes*. Wetland sites may be waterlogged but not wholly submerged, and techniques for investigating them are adapted accordingly.

Historical Background

Free diving to obtain food and other resources, or to recover lost items, has been practiced since antiquity, while equipment to extend the time spent under water and increase the depth reached has been available for many centuries. The most practical solution for early divers was the diving bell, and its many users over some two millennia supposedly include Alexander the Great. In the 1830s the closed diving helmet and attached watertight suit with air pumped via a hose from the surface was developed, and this practical combination (with many technical refinements) remains in use today.

Helmeted divers with surface-supplied air, usually heavily weighted to maintain contact with the bottom, were mainly employed for engineering and salvage work. Sometimes salvage

involved the recovery of valuables from historic shipwrecks, as from the *Mary Rose* in 1836 by John and Charles Deane, who had patented an early form of the helmet diving system (Rule 1982: 42–47). But such activities were primarily commercial, scant attention being paid to the archaeological significance of the finds. The salvage ethos, particularly treasure hunting, has created tensions between archaeologists and commercial salvers which endure to this day.

On 24 August 1854 three professors from the University of Geneva formed an archaeological diving team (surely the first ever) in which one acted as tender, another operated the air pump, while the third (Professor von Morlot) descended three meters to investigate the remains of prehistoric pile dwellings in Lake Zurich (Delgado 1997: 236–237). In 1867 Rev. R. J. Mapleton from Poltalloch on the west coast of Scotland investigated the submerged remains of a crannog (lake dwelling) in Loch Coille-Bharr using divers from the nearby Crinan Canal. Some years later Odo Blundell, a Dominican monk, dived on other crannogs in Scotland using standard diving equipment (Morrison 1985: 4–6). Blundell was a conventional archaeologist who recognized that the potential of sites under water could only be fully realized by archaeologists who were able to dive. Unfortunately, his example was not widely followed by others, and archaeology under water during the first half of the twentieth century was characterized by the activities of divers (by implication heroic but intellectually marginalized) who brought up uncontextualized finds for examination and study by learned but impractical surface-bound "experts."

In 1942 a French naval officer, Jacques Cousteau, collaborated with an engineer, Emile Gagnan, to produce a regulator which allowed a diver to breathe automatically on demand from a cylinder of compressed air strapped to his back. The "aqualung" (now generally known as Self-Contained Underwater Breathing Apparatus or SCUBA) has greatly simplified the process of diving by removing the need for a hose to the surface and providing three-dimensional freedom of movement in the water akin to weightlessness in space. For the discovery and investigation of sites under water, this system has many advantages, not least in that it has opened up the undersea world to many who might not otherwise have had access to it.

Unfortunately, the first generation of SCUBA explorers, headed by Cousteau, were divers rather than archaeologists, and their projects – perhaps understandably at the time – focused more on public appeal generated by spectacular discoveries than on systematic research. Major excavations of classical shipwrecks in the Mediterranean, notably at Grande Congloué in the south of France (Delgado 1997: 174–175), were disappointing in their outcomes and often destructive in their methodologies. Nevertheless, two of Cousteau's colleagues, Frederic Dumas and Philippe Talliez, subsequently developed strong archaeological sensitivities, and both made major contributions to the early history of the discipline (Dumas 1962).

It fell to a young American classical scholar, George Bass, to bridge the divide between divers and archaeologists. He had been approached by Peter Throckmorton, an experienced underwater explorer and photojournalist. Throckmorton had worked with sponge divers in the Aegean who told him of ancient wrecks off the southwest Turkish coast. One, at Cape Gelidonya, dated to the Late Bronze Age and was threatened by looting. In 1960, with the encouragement of the Turkish authorities, Throckmorton teamed up with Bass to mount an expedition to excavate it (Bass 1967). Bass, a conventional academic archaeologist, learned to dive so he could direct the work at firsthand. Thus, a vital principle was established – archaeology under water must be conducted by trained archaeologists who dive (Bass 1966).

Results of the Gelidonya project were outstanding. They were based on methodologies and recording techniques which followed the well-established precepts of practical field investigation and subsequent analysis, adapted to a watery environment. Much archaeology above and below the water still uses basic survey methods, such as tape measures and grids, while excavation is usually conducted with everyday hand tools (Figs. 1 and 2). Simple mechanical

Underwater Archaeology, Fig. 1 Recording archaeological deposits on a shipwreck using a 1-m grid and plumbing device (Colin Martin)

devices, such as the water dredge and air lift, allow the controlled removal of spoil (Fig. 3). Such approaches, though more laborious and time-consuming than the deployment of remote technologies and industrial salvage methods, are more sensitive and bring the archaeologist into direct contact with the evidence as it unfolds. Archaeology, though a rigorous and systematic discipline, cannot be reduced to uncritical processes. Direct interaction between a sentient human mind trained in archaeological method and the material detritus left by former human activity is a necessary concomitant to interpreting and understanding it. Such an approach is also much cheaper and less likely to go wrong.

This is not to suggest that geophysics and other remote techniques should not be used for wider area searches, survey, and excavation, especially in deeper water where diving may be impractical. However, hightech solutions should not be applied uncritically to archaeological investigations, but brought in as necessary to support or enhance simpler "hands-on" techniques or where depth makes direct diver intervention impractical (Bowens 2009).

Since the late 1960s archaeology under water has been influenced by debates within the wider discipline, notably processual archaeology, with its characterization of cultural evolution as an objective quasi-scientific process driven by external stimuli which can ultimately be explained in absolute terms. This was later countered by a post-processual reaction which argued for more subjective and individualistic interpretations of human behavior, on the part both of past societies and of the archaeologists who seek to interpret them. These debates have influenced concepts of underwater archaeology, for which theoretical frameworks have been proposed by Muckelroy (1978) and Gould (2000). A wide-ranging debate among several leading practitioners in 1981 generated a number of important papers on the philosophy and goals of the discipline (Gould 1983).

Key Issues

Shipwrecks

The investigation of shipwrecks is a distinctive specialization within maritime archaeology. When a wreck's remains enter the archaeological record, they become a closed context created by a single catastrophic event. Everything associated with it was once part of a complex and highly organized human enterprise, frozen at the moment of disaster. From a shipwreck archaeologists can, by analyzing the natural processes of deconstruction, reconstruct to a greater or lesser extent interlocking aspects of the ship's original existence as a self-contained entity. The most significant of these is usually the vessel itself, which on occasion may be preserved almost intact. Examples include the *Vasa* (1627) in Stockholm harbor (Fig. 4), the fourteenth-century Bremen Cog, and the schooners *Hamilton* and *Scourge* lost in Lake Ontario during the War of 1812. (Delgado 1997: 454–456, 72–73, 187) The Baltic Sea, with its low salinity and temperatures, is a particularly rich

Underwater Archaeology, Fig. 2 Area excavation within a grid system on the Armada wreck *La Trinidad Valencera* (1588). A water dredge is being used to remove spoil (Colin Martin)

Underwater Archaeology, Fig. 3 An air lift providing heavy suction to remove sterile overburden on the Armada wreck *El Gran Grifón* (Colin Martin)

repository of near-intact wrecks. Sometimes wrecks settle or disintegrate in such a way as to allow confident reconstructions to be projected from their partial remains, as with the *Mary Rose* (1545) off Portsmouth or the sixteenth-century Basque whaling ship in Red Bay, Labrador (Delgado 1997: 264–266, 336–338).

More frequently, only a small percentage of the articulated hull survives, usually from the lower part which may be pinned to the seabed and protected by ballast or cargo (Fig. 5). In such cases the upper works often decay and disintegrate completely, although isolated components sometimes become buried and preserved during the

Underwater Archaeology, Fig. 4 The *Vasa*, found virtually intact on the seabed in Stockholm Harbor. Some reconstructive work is evident (Colin Martin)

wrecking process, and these may help inform reconstruction. The best-known examples of this category are amphora-carrying classical wrecks, mainly in the Mediterranean (e.g., the first-century BC Roman wreck at Madrague de Giens (Tchernia et al. 1978)), and early modern warships whose holds were often ballasted with boulders or gravel.

Other notable shipwreck excavations include the Bronze Age sites at Ulu Burun and Cape Gelidonya, the Byzantine wreck at Yassi Ada, and the early sixteenth-century Cattewater wreck at Plymouth, Devon (Delgado 1997: 430–432, 84–86, 469–471, 90–91).

A full understanding of the formation processes which have conditioned the characteristics of a wreck site is an essential prerequisite to the interpretation of its structural remains and internal organization. Even where no hull remains have survived, a careful analysis of other archaeological material and its distribution may still provide information about the nature, proportions, and layout of the wrecked ship.

The potential of examining ship remains extending from prehistory into the recent past has in many respects been under exploited by the archaeological community at large. While ship archaeology is a distinctive specialization, it has implications far beyond its immediate technicalities. Watercraft are among the most complex and resource-consuming structures most societies produce, so apart from their intrinsic interest, wrecks may be unique statements of a culture's technical capabilities, exploitation of resources, and social organization. Even for more recent periods, the examination of a wooden ship's hull is akin to speaking to the shipwright who built it and is thus more immediate and objective than the study of ship plans, models, documents, and pictures (though these too, if they exist, may have an important role in an investigation).

A wreck is also likely to produce evidence of a ship's function and sometimes minute details about its final voyage. Trade is probably the most common activity of seafarers, and underwater archaeology has made an enormous contribution to its study, from Bronze Age cargoes in the Aegean to the ubiquitous amphora-carriers of classical times and casualties incurred during the transoceanic voyaging of early modern European powers such as imperial Spain and the Dutch East India Company (Delgado 1997: 19–20, 26–28, 55–57, 221–222, 456–457). War is another function for which material evidence may be found on shipwrecks, from the classical ram found at Athlit in Israel to the integrated artillery-based tactics of the sixteenth century evidenced by the *Mary Rose* and the wrecks of the Spanish Armada (Delgado 1997: 43–44, 264–266, 399–402).

Wrecks often produce evidence of the ancillary equipment used on ships, whereby human power was utilized to row, work the sails, raise anchors, and pump out water. Information about provisioning, stowage, food preparation, and cooking may also be obtained. The monitoring of stores and the issue of rations required the use of weights and measures, and the standards employed often reflect the nationality and origins of the vessel. Shipboard activities such as navigation, medicine, and various craft skills will often be evidenced by specialized equipment, tools, and instruments.

Finally, a ship is home to a socially stratified self-contained community, often for months on end. This generates evidence reflecting in many

Underwater Archaeology, Fig. 5 The wreck of a small Cromwellian warship of 1653 off Duart Point, Mull, Scotland, partially excavated. Although the hull has collapsed, the wreck has sufficient integrity to allow partial reconstruction (Colin Martin)

ways the everyday life, work patterns, and social structures of the parent society on shore. Personal possessions, domestic utensils, clothing, and footwear frequently survive, often in abundance, within a shipwreck context.

From a wider archaeological perspective, this is significant on two counts. First, wet buried environments are especially conducive to organic preservation, and thus material which rarely survives on terrestrial sites may be found in shipwreck assemblages (Fig. 6). Since the material culture of most societies, past and present, is overwhelmingly organic in its makeup (wood, leather, bone, fiber, textile), such survival helps correct a skew towards the inorganic and durable which terrestrial recoveries often imply. This skew is exacerbated by the fact that valuable or attractive items are rarely discarded on land, while (unless salvaged) their survival on a wreck is neutrally determined.

Second, a wreck represents a tightly dated assemblage within a single context. Its date may be established archaeologically by the latest object identified (e.g., a coin) or sometimes, if the event is recorded in documentary sources, as a precise calendar date. Collections of artifacts and samples derived from shipwrecks thus define a secure terminus ante quem, that is, nothing can be later than the determined date of the event unless it is a subsequent intrusion. While some objects may have been old when lost, wreck assemblages, if critically studied, can make valuable contributions to the testing and refinement of established chronological typologies, especially for commonplace items like pottery and clay pipes.

Underwater Archaeology, Fig. 6 An intact mariner's compass of wood with brass fittings uncovered on the Duart Point wreck

It should be emphasized, though it is sometimes argued otherwise, that shipwreck archaeology and commercial salvage are not compatible. From the perspectives of each side, the motives and anticipated outcomes of the other are contradictory and irreconcilable. Salvage seeks to maximize profit for investors by making valuable recoveries (and by implication ignoring or discarding "worthless" ones), while archaeology aims to maximize the disciplined acquisition of knowledge, irrespective of the monetary value of what may be found. The mind-set which drives each activity reflects these very different expectations. Neither side can properly accommodate the goals of the other, and it is up to society through its legislatures to decide in which ways the two activities (each of which may be valid and desirable on its own terms) should be separated and regulated. The superficially appealing argument often advocated by the salvage lobby that shipwreck archaeology can be paid for by selling the recoveries (itself an unacceptable diminution of the heritage resource) is deeply flawed. Most responsibly conducted underwater archaeological projects cost more in rigorous fieldwork, conservation, study, and curation than their recoveries could ever yield in a sale room, while the conflict between returns on investment and archaeological ethics creates a divide which neither side can realistically bridge. In any case most treasure-oriented projects, despite (or perhaps because of) the hype which often accompanies their inception, ultimately fail to hit the jackpot, and any intention to provide archaeological mitigation, however inadequate, is usually first to be abandoned when the going gets tough (Keisling 1994). The reality is that no treasure-motivated salvage of a historic shipwreck (whether or not accompanied by a "tame" archaeologist) has yet produced a final report that would pass rigorous archaeological peer scrutiny. That said, otherwise reputable

archaeologists (above or below the water) who fail to publish their work are just as bad.

Submerged Marine Sites

Rising sea levels due to melting ice, geomorphological processes, or cataclysmic events such as earthquakes have in many parts of the world inundated previously dry land, sometimes preserving elements of former landscapes and the archaeology contained within them. Britain was once joined to the continent by a landmass now known as Doggerland, and until about 6 or 7,000 years ago, some 23,000 km^2 of the southern North Sea extending from Yorkshire to Denmark was still a rolling landscape of hills, rivers, swamps, and coastal margins. Its existence began to be suspected in the early twentieth century when plants, animal bones, and worked flints were brought up in trawl nets. In 1931 the fishing boat *Colinda* recovered a mass of peat from the Ower Bank, 25 miles off Norfolk, in which a barbed antler harpoon point was found. This indicated a former landscape in which Mesolithic hunter-gatherers had been active. Systematic investigation of the area was at first impractical and relied on further chance finds, but in the 1990s Professor Byrony Coles attempted to reconstruct the region by working backwards from its present undersea topography.

These pioneering approaches were dramatically refined by Professor Vince Gaffney of Birmingham University, who with the help of the oil industry has been conducting seismic surveys over the area since 2002. This has allowed detailed 3D mapping of the former landscape, in which topography can be modeled to suggest how it was exploited by its human population and the progress of its slow inundation quantified. The picture has been fleshed out with palaeobotanical and faunal evidence, and the eventual aim is to create a virtual landscape within which probable sites of human activity can be predicted before being investigated in reality underwater (Gaffney et al. 2009).

The potential of this approach has already been demonstrated at Bouldnor Cliff in the western Solent near Southampton, where archaeologists led by Garry Momber are investigating an eroding cliff 11 m beneath the surface which has revealed a buried archaeological landscape incorporating Mesolithic material containing worked wood, hearths, flint tools, food remains, and plant fibers dating to around 8,100 BP. Already, the variety of material evidence – much greater than that normally encountered on terrestrial sites – is suggesting levels of technical competence for this period and region some 2,000 years ahead of what had previously been hypothesized (Momber et al. 2011).

A large number of submerged Mesolithic sites assigned to the distinctive Ertebølle culture have been found off the southern part of Funen Island in Denmark (Andersen 1987). This area may be characterized as the eastern part of Doggerland. One of the sites, at Tybrind Vig, has yielded logboats, paddle blades with complex geometric ornamentation, and a range of artifacts including fish hooks, harpoons, and eelspear prongs (Andersen 1987, 2011). These finds are helping to characterize the Northern European Mesolithic as a far more dynamic and socially advanced culture than studies based on terrestrial sites had previously suggested. The possibility of whole prehistoric landscapes preserved under water awaiting discovery and investigation is currently one of archaeology's most exciting and challenging prospects.

Inundated urban sites have long fired public imagination, and these too are now becoming reality. In 1968 Dr. Nic Flemming discovered a vast complex of submerged walls, rock-cut tombs, and other features in shallow water at Pavlopetri in Laconia near the southern tip of mainland Greece. He returned in 2007 with a team from Nottingham University led by Dr. Jon Henderson and Dr. Chrysanthi Gallou. Over the following years (the project is due to finish in 2013), using a combination of conventional mapping and digital survey, the team has revealed an almost complete town plan covering 9,000 m^2 (Fig. 7). Originally thought to date to the early Mycenaean period (c. 1,600 BCE), pottery now indicates occupation extending back to the Minoan Bronze Age (c. 2,800 BCE), making Pavlopetri the world's oldest known submerged city. Its date range, covering the transition from the Minoan

Underwater Archaeology, Fig. 7 An archaeologist inspects house foundations at the submerged ancient city of Pavlopetri in Greece (University of Nottingham)

to the Mycenaean periods, makes it a key site for investigating urban cultural evolution in the eastern Mediterranean (Henderson et al. 2011). Its role as a harbor adds to its potential for study and links it to the Bronze Age wrecks at Uluburun and Cape Gelidonya (of c. 1,300 and 1,200 BCE, respectively) some 400 km to the east.

A much later submerged urban site is at Port Royal, Jamaica, parts of which were engulfed by an earthquake in 1692. Serious underwater archaeological work has been undertaken there by the Nautical Archaeology Program of Texas A&M University since 1981, in conjunction with the Institute of Nautical Archaeology and the Jamaican National Heritage Trust. The area immediately around the former harbor slid and jumbled as it sank, destroying much of its archaeological context, but other parts collapsed more or less intact, retaining much of their stratigraphic integrity. Catastrophic underwater deposition of this nature, as with shipwrecks, ensures the preservation of a rich sampling of what was in current use, including organics. The remains of brick and timber buildings, together with their contents, thus provide a unique and comprehensive snapshot of one of the largest late seventeenth-century English colonial ports in the Americas (Hamilton 1984).

Submerged Freshwater Sites

In June 2011 six European nations – France, Switzerland, Germany, Austria, Italy, and Slovenia – were awarded composite World Heritage Site status in respect of 111 sites incorporating prehistoric lake dwellings in the Alpine region. This enormous resource, which provides a link between hunter-gatherer societies, early farmers, and the first European civilizations, has been investigated by underwater archaeologists since the mid-nineteenth century. It is now sustaining one of the most productive programs of modern archaeological research (Suter and Schlichtherle 2009).

Buildings on artificial islands or piles in lakes or estuarine margins are known in many parts of the world. Scotland is particularly rich in such structures, which are known as crannogs (Fig. 8). In recent years their investigation using underwater archaeological techniques and enhanced methodologies has increased. Like the lake dwellings of the Alpine region, they are no longer regarded as marginal or exotic, but as typical habitation sites set within contemporary landscapes with an exceptional capacity to retain a wide range of organic material and environmental evidence (Dixon 2004). They lead into areas of knowledge and understanding their terrestrial counterparts often cannot reach.

Underwater Archaeology, Fig. 8 Modern reconstruction of a crannog in Loch Tay, Scotland (Colin Martin)

Future Directions

Underwater archaeology is not, as it is still sometimes portrayed, a peripheral and slightly suspect domain of macho people in rubber suits, whose work is of little relevance to "real" archaeologists. On the contrary, it should permeate to the core of its parent discipline in all possible ways. It is in the underwater environment – distinguished from other archaeological matrices only by its wonderfully preservative wetness, anaerobic sediments, and relative freedom from human interference – that many of the discipline's most consequential advances will in future be made.

Underwater Archaeology in Bulgaria

Preslav Peev
Institute of Oceanology, Bulgarian Academy of Sciences, Varna, Bulgaria

Geographical Settings

The coast line of the Bulgarian Black Sea has a length of 378 km. The coastal zone is seen as area which is genetically relevant with historical development of continental shelf as these territories were flooded and drying repeatedly.

The exclusive economic zone of the Republic of Bulgaria in the Black Sea has an area of about 35,000 km^2 as the bottom surface is approximately 44,000 km^2. The area of separate morphological components in the Bulgarian sector of the Black Sea is divided into continental shelf – 12,380 km^2, continental slope – 9380 km^2, continental foot – 12,970 km^2, and abyssal bottom – 8680 km^2. Considering that land territory of Bulgaria is about 111,000 km^2, it is clear that the prospects for underwater surveys of submerged landscapes and searching for sites related to human presence and utilization of marine resources are huge.

The Last Glacial Maximum shoreline of the Western Black Sea is thus believed to coincide with the 120 m isobath (Filipova-Marinova 2007), which is consistent with the figure reported for Mediterranean stable coastlines by Lambeck et al. (2011). This is a key to the ensuing geomorphological interpretations of the submerged landscapes of the Bulgarian continental shelf.

History of Maritime Archaeology in Bulgaria

Underwater archaeological fieldwork has taken place in Bulgaria since the end of the 1950s. The first underwater archaeological survey in Bulgaria has been held in 1959 at the aquatory of Cape Kallikara (Fig. 1). This expedition was accomplished by the Naval Museum – Varna but unfortunately the results are not published. In the same year, a few months later another expedition has been organized at the aquatory of Cape Maslen nos by National Archaeological Institute with Museum at the Bulgarian Academy of Sciences (Galabov 1960) (Fig. 2). Along the Strandzha mountain coast have been found for the first time lead stocks of antique wooden anchors in the Black Sea.

Between 1960 and the end of the 1980s, dozens of underwater archaeological expeditions took place to many sites in Bulgaria. At the aquatory of Nessebar peninsula, under the leadership of the researchers Ivan Venedikov and Lyuba Ognenova-Marinova, the study of the sunken quarters of ancient Messambria began. In the 1960s, Goranka Toncheva studied the remains of ancient wrecks, anchors, and port facilities on the North Bulgarian Black Sea coast in the areas of Cape Kaliakra, Kavarna, the Gulf of Varna, Cherni nos (Toncheva 1964). Again in the 1960s, Mihail Lazarov investigated the remains of ships and antique anchors on the Southern Bulgarian coast – Pomorie, Sozopol, Urdoviza (Lazarov 1975).

During this period, the Bulgarian underwater archaeology marks its beginning with field survey, which does not require the use of large amount of money. In Bulgaria, the first explorations are conducted entirely by Bulgarian investigators.

In the 1980s, the Bulgarian underwater archaeology started the active exploration of the sunken settlements on the coast, focusing on the issues related to palaeogeographical development of the Black Sea coast (Ivanov 1993; Lazarov 1993).

The most popular institutions for underwater archaeological investigations during this period are the Archaeological Museum in Varna, the Archaeological Museum – Burgas, the History Museum in Kavarna. The Thracology Institute of the Bulgarian Academy of Sciences and the

Underwater Archaeology in Bulgaria, Fig. 2 Finds from the first Bulgarian underwater archaeological survey. (Photo: Archaeological Museum – Varna, Bulgaria)

Center for underwater archaeology in Sozopol of the Ministry of Culture were founded in the 1970s.

Bulgarian underwater archaeology had hard days during the 1990s. Only episodic surveys of submerged prehistoric settlements (at Varna Lake, at the mouth of Ropotamo River and Sozopol) or wrecks (bay of Kiten – first half of the nineteenth century wreck) have been carried out.

For these more than 50 years, dozens of underwater archaeological surveys took place in many sites in Bulgaria. The investigations include submerged prehistoric settlements (Ivanov 1993; Draganov 1995; Angelova and Draganov 2003), quarters of ancient poleis (Lazarov 1975; Ognenova-Marinova 1975, 1980; Dimitrov et al. 1982), wrecks (Porozhanov 2000; Peev 2007, 2014). Over the years, the main achievements of Bulgarian maritime archaeology are discoveries of submerged Late Eneolithic and Early Bronze Age settlements, the first artificial harbor facilities along the Western Black Sea coast, which brought new architectural forms to the coastal cities, surveys of natural reefs used such port facilities, few Antique and Medieval wrecks, etc. In Bulgaria, underwater excavations are carried out on the wreck in Kiten bay (Batchvarov 2009) and on the prehistoric settlements Arsenala (Ivanov 1987), Sozopol, Ropotamo, and Kiten (Draganov 1995; Angelova and Draganov 2003).

A series of international scientific research projects which were dealing with a submerged archaeological heritage of Western part of the Black Sea are realized or ongoing. The results are published as chapters of several monographs (The Black Sea Flood Question 2017; Geology and Geoarchaeology of the Black Sea Region 2011; Submerged Prehistory 2011; Submerged Landscapes 2017, etc.). The scientific results of most recent Black Sea Maritime Archaeology Project are not published yet.

Deepwater Archaeology in Bulgaria

At the beginning of twenty-first century, deepwater archaeology starts to be the newest discipline in marine sciences. The main institution for deep sea archaeology in Bulgaria is the Institute of Oceanology of the Bulgarian Academy of Sciences as well as the Centre for Underwater Archaeology at the Ministry of Culture. Some of the recent deepwater archaeological projects at Skerki Bank in the Tyrrhenian Sea, off the coast of Ashkelon (Israel/Egypt), in the Aegean Sea, and in the Black Sea (Turkey, Bulgaria/Romania

and Ukraine) demonstrated that underwater archaeology can be accomplished with advanced techniques.

Among the principal aims in the Black Sea are the discovery and registration of submerged wooden vessels in the anoxic zone and the marking of targets on the continental shelf that might represent traces of submerged prehistoric settlements. This environment is exceptionally suitable for natural conservation of wood because anoxic waters are not suitable for existence of microorganisms decomposing wood, unlike in basins containing other kinds of water (Turner 1973). The archaeological research in deep sea waters poses a range of difficulties. These include but not are limited to sonar survey, target identification, and excavation (Mindell and Bingham 2001).

For the sonar search is used different types of facilities equipped with side scan sonar, sub-bottom profile, depressor, CTD sensor. Target identification and diagnostics in Bulgarian Black Sea are made by manned submersible equipped with round scan sonar and ROV. Remote excavation, even from ROVs, is still in its infancy and remains outside the range of current technology.

During 2001, the first deepwater archaeological survey was held on western Black Sea shelf (Peev 2004). It was wrought on five polygons in Romania and Bulgaria at depth between 70 and 350 m as more than 100 targets were registered. The main purpose of the sonar survey was registration of bottom-located sites, such as wrecks and submerged settlements.

Some recent deep sea archaeological projects demonstrated that maritime archaeology can be accomplished with advanced techniques.

Types of Underwater Cultural Sites in Bulgaria

In Bulgarian Black Sea, there are all of types of underwater historical and archaeological sites. They are united in four groups according to chronological periods and kinds.

The first group is submerged settlements and necropolis from Prehistoric times previously from the Eneolithic and the Early Bronze Age. The second group is antique quarters and harbor facilities. The third is shipwrecks. The fourth group is anchors.

Prehistoric Sites

The submerged prehistoric settlements bring valuable information about human societies along the sea coasts. The sites provide data of everyday life and human adaptation and also about environmental changes such as sea level fluctuations, climate change, etc. As a rule, they are found during building or dredging activities, and traces of them are house beams, pottery, bone objects. The problem of sunken prehistoric sites is a very serious topic and Bulgarian science has made a significant contribution.

Along the Bulgarian Black Sea coast, at least 18 submerged settlements are known dated to the second phase of the Late Eneolithic and Early Bronze Age (between 6500 and 4000 BP) (Ivanov 1993) and one prehistoric necropolis near Cape Shabla (Peev 2008) as all these sunken sites have been found at depth 6–9 m below present sea level (Fig. 3).

The sites have been defined in the scientific literature as "lake-dwellings" (Shkorpil and Shkorpil 1921). The modern researchers are unanimous that term "lake-dwelling" for the Western Black Sea should be used primarily as *terminus technicus.* Chronologically, they belong to the second phase of the Eneolithic Period and the Early Bronze Age (EAB). Since all of these sites have been damaged by construction work and none have been investigated with the methodology of underwater archaeology, the scientific analysis of these settlements has been limited to the determination of their cultural context and their chronological synchrony. The character and function of the sites have almost never been studied. All 18 settlements found to date lay 6–9 m below present sea level. Detailed analysis of existing results and some new data shows that all of these settlements were situated on the first unflooded river terraces, and not on wooden platforms or on pilots. This conclusion, to a great degree, determines the very characteristic of the habitations. Unfortunately, more sites have been

Underwater Archaeology in Bulgaria, Fig. 3 Clay find from Strashimirovo site. (Photo: Archaeological Museum – Varna, Bulgaria)

destroyed during building and trawling work, which has presented difficulties for the investigators. But despite these challenges, the first investigators of the submerged settlements were entirely correct in identifying the presence of four stratigraphical layers. Later, excavations using the methods of underwater archaeology confirmed these observations.

From the Varna-Beloslav firth, only the "Arsenala" site has undergone underwater investigations, on a small area of 25 m^2 (Ivanov 1987). The major result of these studies was the identification of two cultural layers (the Eneolithic and the EBA) without fixed house horizons, as determined from the cultural stratifications on the land. This is a result of the fast rising of the sea level (Peev 2014). The beams of the houses remain in situ and this led to the wrong conclusion that these beams were part of a wooden platform on which the ancient houses were built. Typical for the "Arsenala" site is the massive Early Bronze Age layer, which reaches a thickness of 3.5 m. Below it is situated a layer about 0.90 m thick, which is rich with sea mollusks. This layer is a hiatus for artifacts. The lower layer contains Eneolithic pottery, house beams, and animal bones. The thickness of this lower layer is also around 0.90 m.

Unlike the Varna-Beloslav Lake, along the South Bulgarian coast two of the sunken Prehistoric settlements have been investigated with comparative success: one at the aquatory of the harbor of Sozopol and one at Cape Urdoviza.

A data of prehistoric necropolis was obtained from the area of Cape Shabla (Peev 2008). Two burial sites are present, the first is at 6.5 m below present level, the other at 3.5 m below present level. These could be dated to the Eneolithic. The Sea level along the Bulgarian coast was at least 7 m below present (Peychev and Peev 2006). Without doubt the necropolis is related to the settlements Shabla I and/or Shabla II (Todorova 1984). The necropolis has not been studied.

Antique Sites

In Antiquity, especially after the Hellenic colonization, the port systems along the West Pontic coast expanded. From the Bulgarian Black Sea coast, a series of sunken ancient harbor artificial structure (Karantinata, at cape Galata, Sozopol) (Dimitrov et al. 1982) and parts of residential quarters of the Hellenic poleis are known (Bizone, Messambria) (Ognenova-Marinova 1975, 1980; Preshlenov 2008).

Until now, unequivocal evidence for an artificial harbor at Bizone has not been found (Toncheva 1970). Dimitrov and Orachev (1982) have described the harbour as being natural. There is evidence for the existence of an artificial structure in the eastern part of the Gulf of Kavarna at a depth of 3 m. During an underwater archaeological expedition in 2005, traces of buildings were found at depths of up to 3.5 m. In the modern port of Kavarna, a stone anchor, amphorae from the first c. AD and a coin from Hadrian's reign have been found (Salkin 2009). According to the findings, the harbor complex operated from the first to

second century AD until the end of the sixth century AD.

In the Gulf of Varna, four ancient ports are known (Kastritsi, Odessos, Karantinata, and Galata), and two of them have harbor structures – Karantinata and Galata (Toncheva 1964).

Shipwrecks

A preserved wooden wreck discovered at a depth of 171 m in the anoxic zone of the Black Sea is regarded as particularly intriguing from a scientific point of view. This is the first time that remains of ancient and medieval shipwrecks are registered at such depth in the Bulgarian Black Sea continental shelf. The site is located to the East of Cape Cherni nos on Bulgarian economic zone. The analysis showed that this is a ship from the end of sixteenth century.

A comparatively large wooden ship with a preserved length of 15 m was discovered at a depth of 81 m. The wreck is situated to the South-East of cape Kalliakra on the Varna parallel.

The most ancient wreck in deep-sea was found at depth 81 m to the East of Varna. The target is 13 × 4 m in size. The site is the amphorae cargo of an ancient ship (Fig. 4). The amphorae accumulation has a length of 7–8 m and a width of 1 m. Occurrences of amphorae are not rare in the Black sea region. The amphorae are made of yellow-brown to pink clay with a height of 101 cm and width 53 cm. This type of amphorae is distinctive for its outstanding height varying from 100 to 110 cm. The body is slim, set as a cone on a thick, high cylindrical foot. The mouth is also cylindrical and proportional to the size of the vessel. The crown is angularly building out. The handles are massive and oval in their cross-section. Chronologically, this type of amphorae is referred to the second–third century AD (Fig. 5).

The wreck site is located southeastern of cape Kaliakra on the parallel of Varna. The depth of wreck is 86 m. It presents an excellent preserved wooden sailing boat with length 52 m and width 8 m (Fig. 6). The ship is sunk on kell. The bowsprit was projecting to the bow and close under it could be seen the contours of the figurehead (probably female). The site presents two mast schooner. This type of ships is widespread in the nineteenth century including the Black Sea region. At this moment, more precise dating of the ship is impossible to be made, but according to the anchor type and ship structure, it could be referred to second half of the nineteenth century. The presence of female figure suggests that the origin of the ship is Western European.

Another one wreck has been found at depth 137 m. It is present a wooden sailing boat with length 35 m and width 6 m. The high of the site is

Underwater Archaeology in Bulgaria, Fig. 4 Amphorae cargo of ancient wreck. (Photo: Author)

Underwater Archaeology in Bulgaria, Fig. 5 Amphora dated second–third century AD. (Photo: Author)

up to 6 m over the surrounding relief. The shipwreck is lying on keel and there is no heel.

Anchors

Along the Western Black Sea coast are found a few hundred anchors including stone with groove and holes, wooden with stone and lead stocks, and iron (a several types) (Catalogue 1982; Hristov 2013) (Fig. 7). Most of them are coming from Bulgaria (especially stone anchors). Anchorages are very important for maritime history and archaeology because they provide additional information about navigation in the Black Sea region. It is frequent around anchorages be no findings in archaeological context.

The sites are located in area of intensive trawling of fishing vessels for hunting of rapana and turbots. Therefore, it is necessary the sites have to be studied prior to being caused damage to their integrity. The danger of destruction or injury of the sunken ancient ships is quite real.

Multidisciplinary marine investigations of archaeologists, oceanographers, and ocean engineers demonstrated that the deep-sea archeology has a great potential. It is appropriate that the areas where finds are expected to be declared as protected underwater areas. The outcome of the conducted research shows that the Bulgarian Black Sea region has a high potential for marine deepwater archaeological investigations. The use of contemporary underwater technology and equipment (ROVs and AUVs, sonar scans, etc.)

Underwater Archaeology in Bulgaria, Fig. 6 Wreck site located southeastern of cape Kaliakra (nineteenth century). (Photo: Author)

Underwater Archaeology in Bulgaria, Fig. 7 Types of lead stocks from wooden anchors from Bulgaria. (Photo: Author)

enables the collection of a large amount of data sufficiently adequate for the layout and chartering of the archaeological map of the deep sea part of the Black Sea.

Bulgaria: The National Legislation on Underwater Heritage

The first law on Bulgaria's underwater areas was adopted within the Fifth session of the Ninth Popular Congress of 08.07.1987 (SG, № 55/1987). On 28.01.2000, the Bulgarian Parliament adopts the Law on marine areas, internal waterways, and ports of Bulgaria (SG, № 12/2000). According to the Law, internal maritime waters include the area from the shore to the exit lines connecting Capes Caliacra, Tuzlata, and Ekrene; from the Gulf of Varna – between Cape St. Constantine and Cape Ilangik; from the Gulf of Burgas – between Cape Emine and Cape Maslen and between Cape Maslen and Cape Rohi.

Bulgaria's marine territorial waters stretch for 12 nautical miles, with a total area of 9000 km^2 over which Bulgaria exercises its sovereignty. The adjacent area stretches for 24 nautical miles from the exit lines, and represents the area where Bulgaria exercises control when customs, tax, border, or health procedures are infringed.

An area of major economic interest for Bulgaria is, according to Order № 77/07.01.1987 of the State Council, the area stretching over a distance of 200 nautical miles from the exit lines.

In 1997, an Agreement was concluded with Turkey, with a similar agreement pending with Romania. With regards to performing scientific research, Bulgarian legislation provisions that any scientific studies carried out in the abovementioned territories shall be performed by responsible Bulgarian institutions, based on programs and projects having prior approval from

competent Bulgarian authorities. The means of protecting cultural heritage are provisioned in the national legislation (laws and government decisions), as well as by the international conventions ratified by Bulgaria.

The most important law on the cultural heritage of the Republic of Bulgaria is the Law on Cultural Heritage (Published in SG № 19 of 13.03.2009, republished with changes in SG № 66 of 23.07.2013). In this law, the protection and conservation of cultural heritage, including nonmaterial, industrial, underwater, and cultural landscape, is provisioned in detail. The Law on Cultural Heritage provisions detailed measures of protecting the archaeological heritage on the territory of the Republic of Bulgaria. Through Ordinance № N-00-0001 of 14.02.2011 regarding the performance of on-site archaeological studies, issued by the Minister of Culture, published in the SG № 18 of 1.03.2011, with the latest changes and completions published in SG № 30 of 17.04.2012, there are established all the activities that can be performed on-site within the archaeological studies realized. Ordinance no. N-2 of 6.04.2011 stipulates the creation, maintenance, and provision of information within the automated informational system "Archaeological Map of Bulgaria," issued by the Minister of Culture and published in the SG № 32 of 19.04.2011.

The Centre for Underwater Archaeology at the Ministry of Culture operates in Bulgaria. In 1978, Base for maritime research was established in Bulgaria, which in 1986 was renamed as Center for maritime history and archaeology. Since ,1991 the Center has its current name. The first leaders are Kalin Porozhanov and Ventsislav Popov, followed by Hristina Angelova and Kalin Dimitrov (Porozhanov and Lazarov 1994–2002) This is a state cultural institute to protect the underwater archaeological heritage of the Republic of Bulgaria. Its activity is set up through the Law on Cultural Heritage. The Centre for Underwater Archaeology coordinates the activities related to the management and study of underwater archaeological heritage, having a Register of underwater cultural heritage.

Conclusions

The shelf zone of the Black Sea is subject of intense economic activities – fishing, *Rapana* hunting, dredging of ports and fairways, traces of oil and gas pipelines, underwater cables, yield of oil and gas, etc. This activity causes irreversible damage as to underwater cultural heritage as to biological diversity. In the littoral areas, the cultural heritage is subjected to continuous destructive waves. All this demands systematic surveys aiming studying, conservation, and preservation of the sites. Using of advanced underwater technologies and equipment (side-scan sonars, round-scan sonars, human operated vehicles, research submarines) allows the accumulation of sufficient data for the compilation of the archaeological map of the deep part of the Black Sea and the clarification and understanding of marine cultural processes relevant in this region.

The effect of the study of the Bulgarian underwater cultural heritage and submerged landscapes is expected to change the existing ideas about the nature of some geological events occurring through the Holocene on the Western Black Sea coast, which have reflected on the prehistoric cultures and historical development in the South-Eastern Europe. At the moment are known more than 100 submerged archaeological sites (settlements, wrecks) and potential archaeological landscapes on the littoral zone as well as on the continental shelf across Bulgarian marine territory. The preliminary results showed that the Western Black Sea continental shelf has a great potential for future marine exploration in the area of underwater archaeology in the Pan-European context.

Underwater Cultural Heritage: International Law Regime

Tullio Scovazzi
International Law Department of Law, University of Milano-Bicocca, Milan, Italy

Introduction

The greatest museum of human civilization lies on the seabed. Until the nineteenth century, almost 5% of all seagoing ships were lost every year, be it for storms, incidents of navigation, or naval battles.

Today, the capacity of some states and private entities to use advanced technological means to explore the seabed at increasing depths – for instance, the wreck of the *Titanic* was found in 1985 at 3,798 m below the sea level – not only allows access to a huge cultural heritage but also entails the risk of such heritage being looted or used for private commercial gain.

Key Issues

Different Models in National Legislation

Different approaches can be found in national legislation, based on the priority that the states concerned give to public or to private interests. Two examples are given hereunder.

In Italy, the underwater cultural heritage found within the 12-mile territorial sea falls under the general regime set forth in the "Code of Cultural Properties and Landscape" (Legislative Decree 22 January 2004, No. 42). Research in the field of archaeological and cultural properties is reserved to the Ministry for Cultural Properties and Activities or to the public or private subjects who have been authorized by the ministry. Anyone who fortuitously discovers cultural properties is bound to inform within 24 h the competent public authority. The removal and taking into custody of the properties are permitted only where there is no other means to ensure their security until the intervention of the public authorities.

All the cultural properties found by anyone in the subsoil or on the seabed belong to the state demesne, if immovable, or to the inalienable patrimony of the state, if movable. The finder is entitled to a reward which is paid by the ministry and cannot exceed one-fourth of the value of the properties (if they are found at sea, the reward corresponds to one-third of their value, as provided by the 1942 Navigation Code). The reward may be paid either in money or through the cession of part of the properties.

The state and the other public institutions are bound to ensure the use of cultural properties for the public benefit. Initiatives for the preservation and promotion of cultural properties may be sponsored through contributions by private subjects.

The Italian legislation is a clear example of a regime based on priority given to the interest of the state to preserve the cultural heritage for the purposes of public interest, in particular, research and exhibition. Private interests are given a limited weight and are subject to state authorization.

The US courts apply to the underwater cultural heritage the law of salvage and law of finds, belonging to the body of admiralty law. In many countries, the notion of salvage is only related to the attempts to save a ship or property carried by it from imminent marine peril. But the US courts apply the concept of salvage also to ancient sunken ships and to objects removed from wrecks which, far from being in peril, have been lost since long time.

For example, the US Court of Appeals for the Fourth Circuit in the decision rendered on 24 March 1999 (case *R.M.S. Titanic, Inc. v. Haver*) stated that the law of salvage and finds is a "venerable law of the sea." It is said to have arisen from the custom among "seafaring men" and to have "been preserved from ancient Rhodes (900 BCE), Rome (Justinian's *Corpus Juris Civilis*) (533 CE), City of Trani (Italy) (1063), England (the Law of Oleron) (1189), the Hanse Towns or Hanseatic League (1597), and France (1681), all articulating similar principles." Coming to the practical result of such a display of legal erudition, the law of salvage, which applies where the owner of the wreck is known, gives the salvor a lien (or right in rem) over the object until a reward is paid to him by the owner. The law of finds, which applies when the owner of the wreck or the sunken objects is not known, means that "a person who discovers a shipwreck in navigable waters that has been long lost and abandoned and who reduces the property to actual or constructive possession becomes the property's owner."

The fact remains that the body of "the law of salvage and other rules of admiralty" is today typical of a few common law systems, but is a complete stranger to the legislation of the majority of other countries. For instance, no Italian lawyer (with the laudable exception of a few scholars) would today know what this "venerable" law is, despite the fact that the cities of Rome and Trani, which are said to have contributed to it, are located somewhere in the Italian territory. Nor is it understandable how a body of rules that is said to have developed in times when nobody cared about the underwater cultural heritage could today provide any sensible tool for the protection of the heritage in question. Yet it seems that some American courts are endowed with extraordinary qualities: They have access to all the ancient sources from where such a "venerable law of the sea" can be inferred, they know all the mysterious languages in which the relevant rules have been written, and they are able to interpret such rules correctly and seize the intrinsic consistency between one source and the other. This is impressive indeed.

But those who are not impressed by such a display of legal erudition are inclined to suppose that the almost theological expressions employed to support the application of the law of salvage and the law of finds (such as "return to the mainstream of commerce," "admiralty's diligence ethic," and "venerable law of the sea") are dubious euphemisms. They disguise a "first-come-first-served" or "freedom-of-fishing" approach based on the destination of underwater cultural heritage for the private interest of the finder. Private appropriation and commercial sale are the most likely destiny of the removed artifacts which are considered as "market instruments."

In a number of cases, American courts have granted rights on the basis of the law of finds to treasure hunter corporations which claimed ownership over gold, silver, and artifacts taken from sunken Spanish galleons, such as the *Nuestra Señora de Atocha* (sunk in 1622) or *San Christo del Valle* and *Nuestra Señora de la Concepción* (both sunk in 1715). However, by a judgment on 21 July 2000 on the case of the Spanish vessels *La Galga* and *Juno*, lost, respectively, in 1750 and 1802, the US Court of Appeals for the Fourth Circuit dismissed the claims of the salvor and decided that the rights of a the state of Spain over state ships and property carried by them are not subject to prescription unless they are explicitly renounced by the state concerned. More recently, the US District Court, Middle District of Florida, Tampa Division, by an order made on 22 December 2009, ordered the salvor to return to Spain 594,000 silver coins and other artifacts removed from the wreck of the Spanish galleon *Nuestra Señora de las Mercedes*.

Sometimes coastal states have resorted to regulations applying on a case-by-case basis. For example, by Order No. 14 of 1995, Ireland

defined the site of the wreck of the British liner *Lusitania*, hit in 1915 by a torpedo launched by a German submarine, as a restricted area where no person is allowed to "tamper with, damage, or remove any part of the wreck."

The Counterproductive UNCLOS Scheme

At the international level, the main instrument applying to all kinds of marine activities is the United Nations Convention on the Law of the Sea (hereinafter: UNCLOS), a treaty adopted in 1982 and today (August 2018) binding on 168 parties. Within such a comprehensive achievement of codification, composed of 320 articles and 9 annexes, only 2 provisions (Arts. 149 and 303) are devoted to the underwater cultural heritage (Strati 1995). Yet the UNCLOS regime for underwater cultural heritage is largely insufficient and, as regards the effects of Art. 303, para. 3, can even be considered as counterproductive.

Art. 303, para. 1, UNCLOS puts forward a very general obligation of protection of underwater cultural heritage, providing that "States have the duty to protect objects of an archaeological and historical nature found at sea and shall co-operate for this purpose." Although in a very convoluted wording, para. 2 grants the coastal states the right to establish a 24-mile contiguous zone (in most cases, 12 miles of territorial sea and 12 miles of contiguous zone) for the objective of protecting archaeological and historical objects. No specific provision is included in the UNCLOS for the underwater cultural heritage found within the 200-mile exclusive economic zone. However, para. 3, at least in its English official text, subjects any obligation of protection and conservation of the underwater cultural heritage to a completely different set of rules:

> "Nothing in this article affects the rights of identifiable owners, the law of salvage and other rules of admiralty or laws and practices with respect to cultural exchanges."

It thus appears that salvage law and other rules of admiralty are given an overarching status by the UNCLOS. If there were a conflict between the objective to protect the underwater cultural heritage, on the one hand, and the provisions of salvage law and other rules of admiralty, on the other, the latter would prevail. This means that, availing himself of the principle of freedom of the sea, any person on board a ship could explore the continental shelf adjacent to any coastal state, bring archaeological and historical objects to the surface, become their owner, carry them into certain countries, and sell them on the private market.

If this is the case, there is no guarantee that the objects are disposed of for the public benefit rather than for private commercial gain. Nor could a state which has a direct cultural link with the objects prevent the continuous pillage of its historical heritage. The danger of a "first-come-first-served" or "freedom-of-fishing" approach in the field of underwater cultural heritage is far from being only theoretical. Art. 303, para. 3, of the UNCLOS can be seen as oriented more to the protection of appropriation or looting of underwater cultural heritage than to the protection of the heritage itself.

The second relevant UNCLOS provision (Art. 149) deals with the underwater cultural heritage found in the so-called Area, that is, the seabed beyond the limits of the 200-mile exclusive economic zone of coastal states:

> "All objects of an archaeological and historical nature found in the Area shall be preserved or disposed of for the benefit of mankind as a whole, particular regard being paid to the preferential rights of the State or country of origin, or the State of cultural origin, or the State of historical and archaeological origin."

While vague in its content, Art. 149 shows a preference for those uses of archaeological and historical objects that ensure the "benefit of mankind as a whole." Private interests are given little weight, if any. Some categories of states which have a link with the objects are granted preferential rights, although Art. 149 does not specify the content of these rights and the manner in which they should be harmonized with the concept of "benefit of mankind as a whole."

The 2001 UNESCO Convention

On 2 November 2001, the Convention on the Protection of the Underwater Cultural Heritage (hereinafter: CPUCH) was adopted in Paris with the United Nations Educational, Scientific and Cultural Organization (UNESCO) (Camarda et al.

2002; O'Keefe 2002; Garabello et al. 2003; Dromgoole 2006, 2014). It applies to "all traces of human existence having a cultural, historical or archaeological character which have been partially or totally under water, periodically or continuously, for at least 100 years" (Art. 1, para. 1, *a*).

The CPUCH may be seen as a reasonable defense against the counterproductive regime of the UNCLOS. The basic defensive tools are the elimination of the undesirable effects of the law of salvage and finds and the exclusion of a "first-come-first-served" approach for the heritage found within the exclusive economic zone:

Under Art. 4 of the CPUCH:

> "Any activity relating to underwater cultural heritage to which this Convention applies shall not be subject to the law of salvage or law of finds, unless it:
> (a) is authorized by the competent authorities, and
> (b) is in full conformity with this Convention, and
> (c) ensures that any recovery of the underwater cultural heritage achieves its maximum protection."

This provision is to be understood in connection with Art. 2, para. 7, of the CPUCH ("underwater cultural heritage shall not be commercially exploited") and with the rules contained in the annex, which form an integral part of the CPUCH. In particular, according to rule 2 of the annex:

> "The commercial exploitation of underwater cultural heritage for trade or speculation or its irretrievable dispersal is fundamentally incompatible with the protection and proper management of underwater cultural heritage. Underwater cultural heritage shall not be traded, sold, bought or bartered as commercial goods."

While not totally excluding the application of law of salvage and law of finds, the CPUCH regime has the practical effect of preventing all its undesirable effects.

To fill the gap left open by the UNCLOS, the majority of the countries participating in the negotiation for the CPUCH were ready to extend the jurisdiction of the coastal state to the underwater cultural heritage found within the exclusive economic zone. However, a minority of states assumed that the extension of the jurisdiction of coastal states beyond the 12-mile limit of the territorial sea would have altered the delicate balance embodied in the UNCLOS between the rights and obligations of the coastal state and those of other states within the exclusive economic zone.

To find a compromise, the CPUCH includes a three-step procedure, based on, first, reporting; second, consultations among the states having a verifiable interest to the underwater cultural heritage concerned; and, third, urgent measures to be taken by the coastal state, acting on behalf of the state parties as a whole and not in its own interest.

The annex to the CPUCH sets forth a number of rules concerning activities directed at underwater cultural heritage. They are divided into different sections, namely, general principles; project design; preliminary work; project objective, methodology, and techniques; funding; project duration/timetable; competence and qualifications; conservation and site management; documentation; safety; environment; reporting; curation of project archives; and dissemination.

The text of the CPUCH, which was the outcome of a long-lasting negotiation, could not be adopted by consensus. It was put to vote (87 states in favor, 4 against, and 15 abstentions). Some states could not accept the coastal state's right to adopt provisional measures and the regime applying to warships. However, not only the great majority of developing countries but also several among the industrialized countries cast a positive vote (e.g., Australia, Canada, China, Japan, New Zealand, the Republic of Korea, Austria, Belgium, Denmark, Finland, Ireland, Italy, Luxembourg, Portugal, and Spain).

The CPUCH has entered into force on 2 January 2009 and is today binding only on 60 states. Sadly enough, it appears that the sensible message coming from the CPUCH has not yet been fully appreciated.

The Agreements Relating to Specific Wrecks

Art. 303 of the UNCLOS does not prejudice "other international agreements and rules of international law regarding the protection of objects of an archaeological and historical nature" (Art. 303, para. 4). In fact, some specific agreements

have so far been concluded by states interested to protect wrecks of particular importance for their national historical and cultural heritage. These agreements provide for forms of cooperation between the coastal and the flag state.

Reference can be made to the 1972 agreement between Australia and the Netherlands concerning old Dutch shipwrecks, namely, the *Batavia*, the *Vergulde Draeck*, the *Zuytdorp*, and the *Zeewijk* which sank, respectively, in 1629, 1656, 1712, and 1727; the 1989 exchange of notes between South Africa and the United Kingdom on the wreck of the British warship *Birkenhead* (sunk in 1852); the 1989 agreement between France and the United States on the wreck of the *Alabama*, belonging to the Confederate States of America and lost in battle in 1864; the 1997 memorandum of understanding between Canada and the United Kingdom on the exploration, recovery, and disposition of the *HMS Erebus* and *HMS Terror*, two wrecks lost during the attempt made in 1846 by Sir John Franklin to search for the Northwest Passage; the 2001 agreement between France and the United States on the French wreck of *La Belle*, which sank in 1686 off the coast of Texas; and the 2000 agreement (not yet in force) between Canada, France, the United Kingdom, and the United States concerning the shipwreck of the British liner *Titanic*, sunk in 1912.

Underwater Sites in Archaeological Conservation and Preservation

Thijs J. Maarleveld
Maritime Archaeology Programme, University of Southern Denmark, Esbjerg, Denmark

Introduction

Exceptional preservation is one of the reasons why underwater cultural heritage stands out (Fig. 1). This applies both to sites occurring at the water bottom's surface and to those that are buried deeply in underwater sediments. The waterlogged, anaerobic, and often anoxic conditions warrant that not just stone, ceramics, and other durable materials are preserved but all kinds of organic materials – artifacts and ecofacts – as well. This applies to sites of all periods, including early prehistory (Fig. 2). It is one of the aspects that define the high resolution of archaeological information contained in submerged wetland sites and in sites issuing from wreck.

Exceptional preservation, however, does not mean that the issues involved in archaeological conservation and preservation are any less complicated. Quite to the contrary. Paradoxically, exceptional preservation translates into a high level of vulnerability of sites, contexts, assemblages, and individual objects. All interference disturbs the chemical and physical equilibrium between archaeological material and its environment. That is true on land but is even more pointedly the case for underwater environments. As a consequence of growing attention for underwater

Underwater Sites in Archaeological Conservation and Preservation, Fig. 1 The remains of a seventeenth-century shipwreck and the sculptures adorning its deck equipment are a telling example of how exceptional submerged conservation conditions can be. The Dutch cargo vessel, commonly denoted as "The Ghost Ship" (Eriksson and Rönnby 2012), sits upright at a depth of 130 m in the Baltic. © Deep Sea Productions

Underwater Sites in Archaeological Conservation and Preservation, Fig. 2 A Mesolithic antler ax with wooden shaft illustrates the level of conservation of submerged prehistoric sites, in this case at Gamborg Fjord, Denmark, where the unconsolidated site is subject to erosion. © H. Dal

sites – both in research and heritage management – the conservation and preservation of archaeological objects from maritime or waterlogged environments has developed into a specific branch of conservation science (e.g., Pearson 1987; Björdal 2000; Memet 2008). At the start it built heavily on experience with conservation for purposes of display, but research into in situ conservation and preservation of objects and sites in an underwater environment has developed in tandem. It intensified over the last decade (Björdal et al. 2012; Gregory and Matthiesen 2012).

Metals are a special case. Unlike organic materials, the preservation of metals is not exponentially better in an underwater environment. Corrosion and degradation tend to be aggressive, especially in salt water. Iron of different qualities and composition is particularly prone to react strongly. Depending on the material in its vicinity, such as sand and calcareous organic debris, a hard, irregular, and brittle shell tends to form around it. The resulting lumps are called concretions; their significance is unrecognizable and not just to the untrained eye. Despite their ugly appearance, they may be significant information carriers, even if the object which caused their formation has completely dissolved (Fig. 3). For other metals, with the exception of most inert ones, it is as true as for iron that corrosion and degradation processes will slow down and come to a near standstill once a protective cover has formed. These processes will set in with renewed vigor if the equilibrium with the environment is disturbed, even a little.

Providing for as stable an environment as possible is therefore the key to the archaeological conservation and preservation of underwater sites.

Underwater Sites in Archaeological Conservation and Preservation, Fig. 3 Underwater iron objects will transform into so-called concretions, ugly lumps of which the significance eludes the casual observer. Yet, such concretions can hold significant artifacts or significant archaeological information, even if the object which caused their formation has completely dissolved. The lower image graphically explains that concretions can form relatively quickly and that it is a bad idea to hammer away on them, and not just for archaeological reasons. Definition

Underwater sites have a special place in archaeological conservation and preservation. Underwater environments have warranted exceptional preservation of archaeological traces and remains. Moreover, underwater environments often preserve archaeological remains that dry land environments do not. Objects retrieved from underwater sites have stimulated fundamental conservation science research. The ongoing exploration of the underwater world and the intensified use of underwater and offshore environments have a profound impact on ongoing preservation and degradation as well as on our knowledge about them. Although underwater sites can be extremely vulnerable, they provide abundant information and stimuli for conservation research. Research relating to in situ preservation is rapidly developing, and so are monitoring techniques. Archaeological conservation and preservation of underwater sites is therefore not necessarily more difficult than conservation and preservation on land, but special challenges remain. Just like on land, the central issues to be resolved are not of a technical nature. Rather, they relate to responsible management and to the compatibility of preservation with access, use, and enjoyment of the cultural heritage that underwater sites entail.

Key Issues/Current Debates/Future Directions/Examples

Conservation research and common sense have come together in the deployment of simple but very effective measures of conservation and preservation of underwater archaeological sites. Sandbags and cheap polypropylene netting are not expensive and can be used effectively to isolate vulnerable deposits from mechanical damage, the influence of currents, and biochemical degradation (see examples in Grenier et al. 2006a) (Fig. 4). Gravel has been used in other circumstances (Fig. 5). Underwater ruins have been consolidated with stones, mortar, and various covers.

A key issue in archaeological conservation and preservation of sites is, however, that all efforts depend on their management. General management policies are an important part of it, but specific measures targeted at the archaeological conservation and preservation of a specific site depend on a site management plan, however rudimentary this may be. Management depends on authority and responsibility, and these are only assumed if there is jurisdiction and control. Successful examples of specific in situ measures, whether they are in inland waters, the North Sea, the Baltic, the Mediterranean, the Indian Ocean, the Atlantic, the Caribbean, or the Pacific

Underwater Sites in Archaeological Conservation and Preservation, Fig. 4 The principle of using cheap polypropylene netting to catch sediment in transport in order to cover or backfill exposed remains that are vulnerable to mechanical, chemical, and biological degradation has been well proven in many places of the world. © Martijn Manders – RCE

Underwater Sites in Archaeological Conservation and Preservation, Fig. 5 Gravel is applied as the top layer in the archaeological conservation and preservation of prehistoric sites in Lake Konstanz, Germany. Circum-Alpine pile dwelling sites in Switzerland, Austria, France, Germany, Italy, and Slovenia were inscribed on the UNESCO World Heritage Site list in 2011. (Photo: Joachim Köninger). © Landesamt für Denkmalpflege Baden-Württemberg

(all seven have their examples), are limited to situations where a "competent authority" takes responsibility and almost all examples are in relatively shallow water and close to the shore. Admittedly, these are also the situations where most attention of archaeologists and laypersons has been, but there are many areas where one could wish that developments had taken off as well.

Obviously, zones without any preservation strategies include areas with deficient cultural heritage management. This may be due to the absence of a competent authority, although most countries nowadays have one. It can also happen in cases where heritage management is organized at the local or regional level of government for which the sea is beyond the horizon. Under such circumstances, conservation of underwater sites remains limited or absent altogether. It is remarkable that it can also lead to complete overshadowing of conservation policies at sea. A coastal state has some measure of authority over marine scientific research and an

environmental responsibility in maritime zones such as the Continental Shelf and Exclusive Economic Zone, even though these are international waters (Dromgoole 2013). If heritage is generally organized at a lower government level, it can happen that economic, maritime, fisheries, or defense authorities are completely unaware of heritage conservation principles. As a result they may not notice any need or may take badly informed decisions that directly destroy underwater sites for uninformed reasons, profiting the treasure-hunting industry in sheer contravention of what the same country finds acceptable on land. Examples from Europe, the Americas, and Asia illustrate the point and emphasize the importance of further promotion of the UNESCO Convention on the Protection of the Underwater Cultural Heritage 2001. That such blank zones continue to exist is the more surprising since very remote sites, such as that of the famous *Titanic*, are now subject to protection (Varmer and Aznar 2012).

On a site-specific level, sandbags and other types of cover may be cheap and effective, but they share the dilemma of many measures of archaeological conservation and preservation in that they make in situ remains inaccessible. The purpose is to make sites inaccessible for destructive agents, but it makes them inaccessible for enjoyment as well. The context determines whether that is a problem or not. In the context of the sturdy submerged classical harbor works of Caesarea Maritima, archaeological conservation only enhances visitor experience (Raban 2009). In the context of the exceptional Grotte Cosquer (Clottes and Courtin 1996), underwater conservation follows the logic of conservation of Paleolithic cave art elsewhere, jointly with making the stunning imagery available (Clottes et al. 2005). Conservation and management are not targeted at visitors at all, and visiting through a long siphon with its entrance at 37 m below sea level is complicated anyway. But the simple covering of wreck sites in the Netherlands, Australia, or Sri Lanka does not add to any visitor enjoyment either (Maarleveld 2009; Firth 2011). Other ways to involve and satisfy visitors and other stakeholders are then essential, as no archaeological conservation and preservation can do without them (Carver 2011). The Internet is an obvious medium (Manders et al. 2009). Despite the understandable focus on shallow sites and inshore locations, attention is gradually extending to deeper, and more remote, locations where environmental parameters are nevertheless subject to change after intervention (Leino et al. 2011; Mann 2012).

Yet again metals are a special case. In order to temporarily delay degradation, sacrificial anodes have occasionally been used in archaeological conservation and preservation (MacLeod et al. 1986; Gregory 1999). The technique is well proven in the protection of contemporary metal structures in seawater and especially on ships with rotating bronze propellers. In the absence of sacrificial anodes, electrochemical reactions will quickly consume their steel axles. Despite the efficiency of the technique, it begs the question whether the more general and long-term application in archaeological conservation would be sustainable, given that maritime industries are hard pressed to find alternatives for sacrificial paints and anodes in view of environmental concerns. Nevertheless, the monitoring and management of electrochemical circumstances on underwater sites featuring substantial iron or light metal wreck are important aspects in managing their long-term preservation and enjoyment (Macleod 2006).

This touches on a subject that has been the cause for some confusion. Although archaeological sites include artifacts that become "movable antiquities" on removal, the site as such is immovable. This is as true for archaeological sites resulting from wreck as it is for prehistoric kitchen middens. In discussing relatively recent wreck sites that occur at the surface of the (sea) bottom, it is relatively common to refer to the name of the original craft (Fig. 6). Management of electrochemical processes consists in conservation measures that are specifically targeted at protecting the "object." Nevertheless, such efforts are specifically oriented to preservation in situ and are thus part of conservation and management of the site as a whole. In that sense the efforts are fundamentally different from conservation efforts addressing operating watercraft and other movable items, despite similarity in techniques. It is

important to keep this difference in mind because of the legal differences relating to "immovable sites" and "movable objects" and their consequences for protection, salvage, and treasure hunting. Archaeological conservation and preservation of underwater sites, including those wreck sites that for historical reasons are considered significant, are supported by, find their legal basis in, and should elaborate on spatial protection. Salvage practice, rulings, and contracts derive their meaning from the thing, not from the place. Like any other activity, however, salvage activities are subject to spatial policies, regulations, and permits. They are therefore subordinate to heritage protection policies, which is important to keep in mind.

Although a management plan for a specific site is the obvious context for specific measures of conservation and preservation, more general management plans or policies can include very relevant measures that contribute to long-term preservation. Such measures generally need to be integrated with general management schemes such as spatial planning or policies addressing specific activities, be they offshore exploration or fishing. Integration of specific measures in such general policies or in agreements with industry can add enormously to the archaeological conservation and preservation of underwater sites, both directly and indirectly. Yet again, as so often in these pages, reference can be made to treasure hunting in maritime archaeology. Treasure hunters have started to justify their destructive activities by referring to the impact of deep-sea fisheries. Undoubtedly, it is true that fishing impacts archaeological sites. But that is no reason to replace impact with willful destruction. Both the dredging and fishing industries have shown their willingness to consider responsible policies of impact mitigation. It is not in their interest to do otherwise. Moreover, most deep-sea fishing techniques do not impact the bottom at all (Maarleveld et al. 2013, chapter 10).

In preference of discussing general trends, relatively little has been said on archaeological reserves, parks, and memorials. Obviously, however, they are the perfect examples where site management plans are in place, where at least some of the techniques of archaeological conservation and preservation have been developed and where the experience with managing the compatibility of preservation with access, use, and enjoyment of the cultural heritage is greatest. On the other hand, their number is relatively few and therefore hardly representative for global practices. But a few can be mentioned and add to the discussion. The USS Arizona Memorial in Pearl Harbor is an exceptional case. Although not established for predominantly archaeological reasons, it is certainly the site that attracts more visitors each year than any other underwater site. The wreck site of the French fourth rate navy vessel Célèbre that sank in 1758 in the entrance to Louisbourg fortress in Canada is an example where management and monitoring started in 1961 and intensified through archaeological documentation and improving accessibility to the

vulnerable site for visiting recreational divers in the 1980s (Grenier 1994). The Louisbourg wrecks are managed in conjunction with the Fortress of Louisbourg National Historic Site of Canada. A third example is Florida's Underwater Archaeological Preserves. These reserves have been established in response to extensive looting and take public archaeology and education as their motto (Jameson and Scott-Ireton 2007). Finally, the protective cages that the Croatian Conservation Institute has mounted over classical shipwreck sites should be mentioned (Fig. 7). They protect sites against visitor interference while allowing them a see-through in much the same way as visitors watch wild animals in a classical zoo.

Although one can expect creative developments to continue, underwater sites have begun to play a significant role in archaeological conservation and preservation. This is quite different from a couple of decades ago.

UNESCO (1970) and UNIDROIT (1995) Conventions

Patty Gerstenblith
DePaul University College of Law, Chicago, IL, USA

Introduction

The growth in the international market in art works and other cultural objects following the Second World War prompted the United Nations Educational, Scientific and Cultural Organization (UNESCO) to begin in the 1960s drafting an

international convention to control this trade. In addition, the newly independent, former colonized States sought a means of recovering cultural heritage objects that had been removed during colonialism. The 1970 UNESCO Convention on the Means of Prohibiting and Preventing the Illicit Import, Export and Transfer of Ownership of Cultural Property ("the 1970 UNESCO Convention") was adopted in November 1970; as of mid-2018, there are 137 States Parties.

When a State ratifies an international convention (or treaty), it may view the convention as either self-executing, in which case the provisions of the convention are automatically adopted into national domestic law, or as non-self-executing (or executory), in which case the provisions of the convention must be adopted into national domestic law usually through implementing legislation, although other mechanisms such as administrative measures may be sufficient (O'Keefe 2017: 193–197). Larger, multilateral conventions are typically viewed as non-self-executing. Most market States that have ratified the 1970 UNESCO Convention, with some exceptions, such as the United Kingdom, have enacted implementing legislation. However, variation in the methods of implementation adopted by the different ratifying States, particularly the market States, has resulted in significantly different responses and degrees of effectiveness of the Convention in regulating the international trade.

Recognizing that there were impediments to acceptance of the 1970 UNESCO Convention particularly by European States that follow the civil law, UNESCO asked the International Institute for the Unification of Private Law (UNIDROIT) to draft a new convention to respond to these concerns. The UNIDROIT Convention on Stolen or Illegally Exported Cultural Objects was finalized in 1995. In contrast to the 1970 UNESCO Convention, which is a matter of public international law and operates purely on a State-to-State basis, the UNIDROIT Convention focuses on the creation of private rights of action through adoption of uniform national legislation. The UNIDROIT Convention requires ratifying States to adopt domestic law that implements the convention and, for the most part, does not allow States to opt out of sections of the convention. There are currently 44 States Parties.

Background

The 1970 UNESCO Convention

The UNESCO Convention, in Article 1, defines cultural property as "property which, on religious or secular grounds, is specifically designated by each State as being of importance for archaeology, prehistory, history, literature, art or science" and which belongs to an enumerated list of categories, including paintings, drawings, original works of sculpture, rare manuscripts, coins more than 100 years old, ethnological objects, products of archaeological excavations, and elements of artistic or historical monuments that have been dismembered. Archaeological artifacts that are looted from the ground and sold directly onto the international art market are unknown and therefore undocumented before they appear on the market. Therefore, the requirement of "specific designation" raises particular problems as applied to archaeological objects whose original archaeological context is crucial to developing knowledge and understanding of the past but which is destroyed through looting of archaeological sites. Therefore, one key question is how the various market States respond to the specific designation requirement in their implementing legislation in order to regulate or prevent trade in undocumented archaeological artifacts.

To some States, Article 3 contains the key obligation of the convention, stating: "The import, export or transfer of ownership of cultural property effected contrary to the provisions adopted under this convention by the States Parties thereto, shall be illicit." According to O'Keefe, this provision means that States Parties shall not permit the import of cultural objects whose export from another State Party was illegal (O'Keefe 2017: 136). However, the United States took the position that Article 3 is "a mysterious provision that will not be operative in the United States" (Bator 1982: 377). Rather, the United States views Articles 7(b)(1) and 9 as embodying the core obligations of the convention.

The convention imposes obligations on both market States and countries from which cultural objects originate. Countries of origin have an obligation to protect their own sites and museums, to police their borders, and to educate their people about the values in conserving their cultural heritage. These obligations more specifically include establishing a government agency or service to assist in the preparation of laws for the regulation of cultural objects, establish a national inventory of protected property, promote scientific and technical institutions, and supervise archaeological excavations (Article 5); establishing a licensing system for the export of cultural objects (Article 6); and requiring dealers to maintain registers with information on the origin, supplier, description, and price of items sold (Article 10).

One of the motivating reasons for adoption of the 1970 UNESCO Convention was to provide a means of obtaining restitution to formerly colonized States of cultural artifacts removed during colonialism (Prott 2012: 2). However, this goal was not realized because of objection from the former colonist States and the general principle that international agreements do not have retroactive effect (UNESCO 2015: 22). However, Article 15 provides that States Parties may continue to fulfill obligations under any other international agreement and may enter into additional agreements for the purpose of restituting cultural property removed before the UNESCO Convention's entry into force. In addition, UNESCO established the Intergovernmental Committee for Promoting the Return of Cultural Property to its Countries of Origin as a forum to hear and help negotiate resolution of cultural heritage disputes (Bator 1982: 363–364), although the process has rarely been utilized (Prott 2012: 5).

In order to increase understanding and effectiveness of the convention and, to some extent, out of frustration with the limited implementation of the convention by market States, the States Parties established a Subsidiary Committee in 2013 that would meet on a regular basis. To strengthen understanding and resolve problems of interpretation, the Subsidiary Committee submitted Operational Guidelines to the Meeting of the States Parties in 2015 (UNESCO 2015; Scovazzi and Ferri 2015). The Guidelines note, in particular, the special challenges posed by the categories of products of archaeological and paleontological clandestine excavations, elements of dismembered artistic or historical monuments and archaeological sites, and ethnological and indigenous cultural items, particularly human remains, which are not specifically covered by the convention (UNESCO 2015: 6–7).

The 1995 UNIDROIT Convention on Stolen or Illegally Exported Cultural Objects

For the first two decades, the 1970 UNESCO Convention proved to be fairly unpopular with most of the European market States and received few ratifications. One of the primary reasons for this was that the continental European countries follow the good faith purchaser doctrine by which a purchaser who acts in good faith can obtain title to stolen property after the passage of a relatively short period of time, which varies among different countries. UNESCO therefore asked Unidroit to draft a convention that would pertain to private international law and, among other provisions, would provide a compensation mechanism for the good faith purchaser (Prott 1997).

The Unidroit Convention utilizes the same definition of cultural property as that in Article 1 of the UNESCO Convention. The Unidroit Convention provides that stolen objects should, in most circumstances, be returned to the original owner and illegally exported objects to the country of origin. Fair and reasonable compensation must be paid to a good faith purchaser of stolen or illegally exported cultural objects. The convention also provides a definitive statute of limitations of 3 years from the time the claimant knows the location of the object and the identity of the possessor and, in any case, 50 years from the time of the theft or illegal export. However, a claim for a cultural object that is an integral part of an identified monument or archaeological site or part of a public collection or that is a sacred or communally owned object is subject only to the 3-year actual discovery rule. A significant provision equates illegal excavation with theft when this is consistent with local law. Article 3(2) states, "a cultural object which has been unlawfully

excavated or lawfully excavated but unlawfully retained shall be considered stolen, when consistent with the law of the State where the excavation took place." Characterizing such objects as stolen implicates the domestic law of market States against trading in stolen property. This provision offers a suitable response to the problem of looted and therefore previously unknown and undocumented archaeological artifacts.

To be eligible for compensation, the possessor must have "neither [known] nor ought reasonably to have known that the object was stolen and can prove that it exercised due diligence when acquiring the object" (Article 4(1)). Article 4(4) provides:

> In determining whether the possessor exercised due diligence, regard shall be had to all the circumstances of the acquisition, including the character of the parties, the price paid, whether the possessor consulted any reasonably accessible register of stolen cultural objects, and any other relevant information and documentation which it could reasonably have obtained, and whether the possessor consulted accessible agencies or took any other step that a reasonable person would have taken in the circumstances.

Due diligence thus refers to the conduct of the purchaser in investigating an object's provenance at the time of purchase. Particularly in the realm of antiquities, certain additional factors should be taken as indicating likelihood of theft or illegal export. These include origin in areas with recent large-scale looting, such as Iraq, Syria, and Afghanistan.

Unlike the 1970 UNESCO Convention, which allows States Parties to determine their method of implementation of the convention into domestic law, the UNIDROIT Convention requires that all States Parties adopt the uniform legislation provided in the convention. For that reason and despite the fact that it was drafted to appeal to the European continental States, relatively few market States have ratified it. In fact, several European States, such as Switzerland and Germany, examined the UNIDROIT Convention and then subsequently chose to ratify the 1970 UNESCO Convention because of the latter's greater flexibility. Nonetheless, as will be discussed below, the UNIDROIT Convention has had a significant influence even on States that chose not to ratify it.

Current Debates: Models of Implementation

The United States Senate gave its unanimous consent to ratification of the 1970 UNESCO Convention in 1972, but it specified that the convention would not come into effect until domestic implementing legislation was enacted, which did not occur until 1983. At that point, few market States had ratified the convention. While it took close to 30 years before other major market countries demonstrated interest in the 1970 UNESCO Convention, that situation began to change significantly in the late 1990s and early 2000s. In 1997, France joined the Convention, followed by the United Kingdom and Japan (2002); Sweden, Denmark, and Switzerland (2003); Germany (2007); Belgium and the Netherlands (2009); and Luxembourg and Austria (2015).

Several of these countries decided to ratify the Convention in response to the looting of archaeological sites and museums that occurred during and after the US-led invasion of Iraq in 2003. Switzerland was motivated, at least in part, by the discovery of large quantities of looted antiquities that had been stored in the free transit zone of the Geneva airport by the Italian dealer Giacomo Medici (Watson and Todeschini 2005). Finally, some countries joined in response to their analysis of the 1995 UNIDROIT Convention on Stolen and Illegally Exported Cultural Property. While examining this latter convention, which was drafted to appeal to the European continental countries, these countries realized that its more onerous requirements were not acceptable, whereas the less precise requirements and latitude granted to method of implementation of the 1970 UNESCO Convention made it more attractive. The relative effectiveness of the different models of implementation used by market States may be analyzed, particularly with respect to two issues: the problem of specific designation in the Article 1 definition of cultural property and the ability of a market State to take proactive steps in the case of

emergency situations, such as we have seen in Iraq and Syria.

"Across-the-Board" or Reciprocal Import Restrictions: Implementation of Article 3

Most States Parties grant reciprocal recognition to the export restrictions of other nations when those export restrictions are promulgated as part of their implementation of the 1970 UNESCO Convention. This broad approach to the recognition of other States Parties' export controls implements Article 3 of the Convention. Article 6(b), which states that States Parties "undertake . . . to prohibit the exportation of cultural property from their territory unless accompanied by the . . . export certificate" described in Article 6(a), is an integral part of a trade regulatory scheme. Because export controls operate based on categories of types of objects whose export is restricted, reciprocal import controls similarly apply to categories of types of objects, rather than only to specific, identified objects. This means that an object does not have to have been documented in order to be subject to export and import control, thereby providing an effective approach to the problem of looted and therefore previously undocumented archaeological objects. The implementation schemes of three nations, Australia, Canada, and Germany, are examined as examples of "across-the-board" or reciprocal import restrictions.

Australia. Australia enacted its implementing legislation, The Protection of Movable Cultural Heritage Act, in 1986 before becoming a State Party in 1989 and amended it in 2011. It is perhaps unique among States that have ratified the 1970 Convention in that its import controls apply to all illegally exported cultural objects, regardless of whether the State of origin is a Party to the 1970 Convention. The export control that was violated only needs to be a "law of that country relating to cultural property" (Section 14(1)). In addition, it does not matter when the object was illegally exported from its country of origin, so long as the import into Australia occurred after the effective date of the legislation. Such an object is subject to forfeiture. A person who knowingly violates the import prohibition commits an offense punishable by a fine not exceeding $100,000 or imprisonment not exceeding 5 years or both (Section 14(2)). Australia is reported to be considering strengthening its legislation in the wake of the scandals involving Australian museums that acquired sculptural pieces stolen from Hindu temples from the dealer Subhash Kapoor (Crennan 2016).

Canada. In 1978, Canada enacted broad import and export regulations, pursuant to Articles 3 and 6(b) of the Convention, when it adopted the Cultural Property Export and Import Act ("CPEIA"), R.S.C. 1985, c. C-51 ff. The CPEIA establishes a system of controls on the export of cultural materials from Canada and serves an important function in preserving Canada's cultural heritage (Nafziger et al. 2010: 302–305). This legislation allows the establishment of a list of cultural materials whose export is subject to control through an export permit requirement.

With respect to import controls, the CPEIA applies to "foreign cultural property," defined as "any object that is specifically designated by [a reciprocating State] as being of importance for archaeology, prehistory, history, literature, art or science" R.S.C. 1985, c. C-51, § 37(1). The definition is thus similar to the 1970 UNESCO Convention's definition of cultural property. A "reciprocating State" is a "foreign State that is a party to a cultural property agreement." The Act envisages the possibility that Canada will enter into bilateral and multilateral agreements "relating to the prevention of illicit international traffic in cultural property." While the Act does not specifically refer to the 1970 UNESCO Convention as one such agreement, it is clear that the Convention fits this definition and that the Act's provisions therefore apply to any nation that is a State Party. The operative provisions of the Act are relatively straightforward, stating, "it is illegal to import into Canada any foreign cultural property that has been illegally exported from that reciprocating State" R.S.C. 1985, c. C-51, § 37(2). The import restrictions apply only to foreign cultural property illegally exported after the date on which a cultural property agreement comes into force in both Canada and the reciprocating State. The relevant date for Canada with respect to the 1970 Convention is 1978.

One recurring theme in the implementing legislation of several market States is the question of how the "specific designation" requirement of the UNESCO Convention's definition of cultural property is interpreted. One court in Canada answered this question with respect to Canada's import controls, in R. v Yorke, by holding that a Bolivian Decree restricting the export of textiles sufficiently designated the category of textiles and therefore fit the CPEIA's definition of "foreign cultural property." The court understood the difficulty posed by a specific designation requirement, particularly as applied to the types of archaeological and ethnographic objects that are frequently undocumented before their illegal removal, stating:

> [T]he appellant's submission that, to "specifically designate" cultural property something more was required of Bolivia than what was specified in the Decree, is not tenable. It would not be possible for a nation to create an itemized list of every piece of property to be protected. The categories have been made clear in the Decree . . ., and they apply to the items seized from the appellant. Likewise, the suggestion that the term "weavings" is somehow overly broad and fails to distinguish those "weavings" which are of cultural significance from those which are not, is not persuasive. The term "weavings" is one of common usage and the Decree distinguishes them from property of other types of manufacture. Ms. Bubba-Zamora testified about the weaving tradition in Bolivia. Textiles that are cultural property reveal valuable information regarding ethnic groups and their religious practices. (R. v Yorke (1998), 166 N.S.R. (2d) at 150)

This may be the only judicial interpretation of the specific designation requirement and how it can be satisfied.

Two examples of attempted recoveries of cultural materials under the Canadian Act occurred relatively early in its history, and, in both attempts, it could not be established that the cultural materials had left their country of origin after the date on which the CPEIA went into effect. One involved a shipment of antiquities from Egypt that was seized at Mirabel Airport near Montreal in 1989 (Walden 1995: 208–210). The Egyptian authorities presented evidence that the artifacts had been illegally excavated and smuggled out of Egypt but ultimately were not able to present proof that they had been taken out of Egypt after 1978. A similar episode occurred in the prosecution of a dealer for importing artifacts smuggled out of Nigeria (R. v Heller (1984), 30 A.L.R. (2d) 130 (Q.B.)). This case involved the attempted prosecution of a New York dealer who imported a Nok terracotta sculpture into Canada that had been illegally exported from Nigeria (Shyllon 2000: 221).

Between 1978 and 2000, Canada received 11 requests for returns, 7 of which were successful. Between 2000 and 2007, there were five returns, one each to Peru, Bolivia, and Egypt and two to Colombia (O'Keefe 2007: 149). According to Canada's 2010 report to UNESCO on its implementation of the 1970 Convention, between 2007 and 2010, Canada returned 350 cultural objects to Bulgaria, China, Egypt, Mali, and Nigeria (Canada 2011: 3). According to Canada's 2015 report to UNESCO, between 2011 and 2015, it returned over 21,000 objects to four States: Bulgaria, China, India, and Lebanon (Canada 2015: 5; UNESCO n.d.). The largest seizure and return of cultural artifacts by Canada was the 2011 restitution to Bulgaria of 21,000 cultural objects, including 18,000 ancient coins and other objects such as jewelry, Byzantine crosses, amulets, belt buckles, and bronze eagles (Crawford 2011).

It is a criminal offense to import or attempt to import cultural property in violation of the CPEIA (R.S.C. 1985, c. C-51, §§ 43 and 45). The maximum penalty is a fine in the amount of $25,000 and imprisonment for up to 5 years (R.S.C. 1985, c. C-51 § 45). The only reported conviction under this provision occurred in R. v Yorke, discussed above, involving a dealer who imported textiles from Bolivia (R. v Yorke, 166 N.S.R. (2d) 130 (1998)) (O'Keefe 2017: 240–242).

Germany. Germany enacted implementing legislation for the 1970 UNESCO Convention in 2007. Under this legislation, Germany prohibited the import of any illegally exported cultural objects that had been individually classified in an accessible inventory by the country of origin (termed the "list" or "inventory" principle). (Act implementing the UNESCO Convention of 14 November 1970 on the means of prohibiting and preventing the illicit import, export and

transfer of ownership of cultural property (Act Implementing the Cultural Property Convention) 23.5.2007, BGBl 1 2007, s 6(2) sentences 1–3)). It is widely recognized that this approach is not effective for confronting the problems of the looting of archaeological sites and undocumented artifacts.

In recognition of this limitation and as a response, at least in part, to the widespread looting that is occurring in Middle Eastern countries, in 2016 Germany amended its legislation to deal more effectively with this problem, Act on the Protection of Cultural Property (Cultural Property Protection Act) 8.6.2016, BGBl 1 p 1914 (Peters 2016: 96–97). In so doing, Germany adopted the category principle. This legislation fulfills Germany's obligations under United Nations Security Council Resolution 2199 (2015) to restrict the import of cultural materials illegally removed from Syria after 2011.

The amended legislation creates new provisions for the import of archaeological objects into Germany. The import restrictions no longer require that objects have been inventoried but rather focus on whether a State Party subjects the category of objects to export restriction. Under this legislation, an importer must present documentation that the cultural property was legally exported if it left another State Party to the 1970 UNESCO Convention after 2007, the date of Germany's ratification of the Convention. This shifts the burden to the importer to present such documentation; in the absence of such documentation, the law creates a presumption that the cultural property was unlawfully exported from the relevant State Party after 2007 (Federal Government Commissioner for Culture and the Media 2016: 7). This requirement recognizes that most States require licenses for the export of cultural property and that this provision, moving from a list principle to a category principle, particularly helps to protect archaeological objects.

States that adopt reciprocal import restrictions based on legal export from another State Party have resolved the two key issues in implementation of the 1970 UNESCO Convention. First, they have resolved the question of specific designation by considering that the process of establishing export controls on categories of cultural objects constitutes specific designation. Second, they have provided a proactive response that obviates the need for enactment of special legislation or other steps to respond quickly to crisis situations. As Canada noted in its 2015 Report to UNESCO, "Canada has not required any additional measures to implement UNSCR 2199 for the protection of Syrian and Iraqi cultural heritage. The *Cultural Property Export and Import Act* already prohibits the import into Canada of cultural property illicitly trafficked from these states" (Canada 2015: 9).

Bilateral Agreements

The United States and Switzerland are the only States Parties that require other States Parties to enter into supplementary agreements (termed bilateral agreements or Memoranda of Understanding) in order to implement the 1970 UNESCO Convention. Despite this superficial resemblance, the Swiss legislation differs from that of the United States in several important respects. The Swiss legislation implements Article 3 rather than, as in the case of the United States, Article 9. For this reason, the Swiss agreements are not limited to the categories of archaeological and ethnological materials but, rather, may apply to all types of cultural property.

Switzerland. The Swiss implementing legislation, the Cultural Property Transfer Act ("CPTA"), took effect in June 2005 (Loi fédéral du 20 juin 2003 sur le transfert international des biens culturels). The Swiss legislation permits the Swiss Federal Council to enter into agreements with other States that are Party to the 1970 Convention to protect "cultural and foreign affairs interests and to secure cultural heritage." (CPTA, Article 7). The Swiss legislation defines "cultural property" as "significant property from a religious or universal standpoint for archaeology, prehistory, history, literature, arts or sciences belonging to the categories under Article 1 of the UNESCO Convention of 1970" (CPTA, Article 2(1)).

The Swiss definition does not mention "specific designation" found in Article 1 of the Convention. The agreements include a list of designated artifact types of cultural property by category. This allows the import of objects to be

restricted even if they have not been documented before their illegal removal. While the Swiss agreements are not restricted to archaeological and ethnological materials, they primarily relate to categories of archaeological objects recognized as being of significant importance for the cultural heritage of a State. The Swiss agreements are of potentially unlimited duration and do not need to be renewed. Most of the Swiss agreements are truly mutual in nature in that they call for recognition of Swiss regulations on the export of cultural property, and each agreement has two designated lists of protected cultural properties – one list of Swiss cultural property and the second list for the cultural property of the State with which Switzerland has the agreement.

Officials of the Swiss Ministry of Culture negotiate the agreements directly with their foreign counterparts. The agreements last for an indefinite amount of time, thereby providing a disincentive to trade in the affected cultural objects. The Federal Council can also take additional measures when a "State's cultural heritage [is] jeopardized by exceptional events" (CPTA, Article 8). Unlike the bilateral agreements under the CPTA that implement Article 3, emergency actions taken under Article 8 of the CPTA implement Article 9 of the Convention and may last for only a limited amount of time.

As of 2018, Switzerland has agreements in force with Italy (2008), Greece (2011), Colombia (2011), Egypt (2011), Cyprus (2014), China (2014), Peru (2016), and Mexico (2017) (Switzerland 2016a). Artifacts have been returned to their countries of origin, including Greece, Italy, Egypt, Turkey, Chile, Peru, and Lebanon, although some of these actions do not seem to have been taken pursuant to a bilateral agreement. Switzerland returned a group of 32 artifacts to Egypt in June 2015 pursuant to the bilateral agreement and in conjunction with a celebration to mark the 10th anniversary of the Swiss legislation (n.a. 2015). In 2016, it returned five archaeological artifacts to Italy (Switzerland 2016b).

The CPTA adds criminal provisions for the intentional or negligent illicit import of cultural property or incorrect declaration of cultural property during import or transit. The maximum penalty under the CPTA for intentional violation is a fine of 100,000 Swiss francs or imprisonment of up to 1 year; for negligent violation, the maximum fine is 20,000 Swiss Francs. If the offender acts on a professional basis, the sanction is a fine of up to 200,000 Swiss Francs or jail for up to 2 years (CPTA, Article 24). The CPTA adopts higher duties of diligence for "persons active in the art trade and auctioning business" (CPTA, Article 16).

The Swiss legislation that implemented the 1970 UNESCO Convention also made other changes in Swiss law regulating the art market. Perhaps prime among these were changes in the good faith purchaser doctrine, which permits a seller to transfer title to stolen property to a good faith purchaser and made Switzerland, in the past, a place where title to stolen and looted antiquities could be laundered. These changes have altered the applicability of the doctrine to acquisitions of art and cultural objects making Switzerland less desirable as an intermediate market country. While other countries now serve the function of transit point, Switzerland still seems to host a robust art trade.

United States. Although the United States signed the UNESCO Convention in 1970 and the Senate gave its unanimous consent to ratification in 1972, the Senate also required the adoption of implementing legislation before the convention would have domestic legal effect. This implementing legislation, the Convention on Cultural Property Implementation Act ("CPIA"), was signed into law in early 1983 (19 U.S.C. §§ 2601–13). The United States implemented as substantive provisions only Articles 7(b)(1) and 9 but also refers to other articles of the convention. It adopted the convention's Article 1 definition of cultural property but explicitly eliminates the specific designation requirement.

Article 7(b)(i) states that States Parties should "prohibit the import of cultural property stolen from a museum or a religious or secular public monument or similar institution in another State Party to this Convention after the entry into force of this Convention for the States concerned, provided that such property is documented as appertaining to the inventory of that institution."

Because this provision refers to traditional theft from documented collections, its implementation has not been problematic.

Article 9 of the UNESCO Convention states:

> Any State Party to this Convention whose cultural patrimony is in jeopardy from pillage of archaeological or ethnological materials may call upon other States Parties who are affected. The States Parties . . . undertake, in these circumstances, to participate in a concerted international effort to determine and to carry out the necessary concrete measures, including the control of exports and imports and international commerce in the specific materials concerned. Pending agreement each State concerned shall take provisional measures to the extent feasible to prevent irremediable injury to the cultural heritage of the requesting State.

The first difficulty with the implementation of Article 9 is that several key terms, including "cultural patrimony," "jeopardy," and "pillage," are left undefined. "Jeopardy" would seem to involve some sense of futurity – that is, it encompasses a situation in which there is a threat or danger of pillage, as well as contemporaneous, ongoing pillage of the cultural patrimony. O'Keefe focuses more on the question of the extent to which these terms imply a requirement of a crisis or emergency situation and concludes that this is not necessary:

> [P]illage and jeopardy of a cultural heritage occur where the remains of a particular civilization are threatened with destruction or extensive movement abroad or when the sale of certain archaeological objects on the international market sets off a broad campaign of clandestine excavations leading to the destruction of important archaeological sites.... [I]t should not be considered open to a State Party to refuse to act on the ground that, in its opinion, the pillage complained of was not in fact putting the cultural heritage of the requesting State in danger.... Article [9] was against illicit traffic in cultural objects, and . . . the requesting State should not, therefore, be required to produce evidence as to the degree of damage or size of the illicit trade in these objects. (O'Keefe (2017: 168))

The last section of Article 9 includes the concept of "irremediable injury" in considering a State Party's obligation to act quickly to avoid such harm. "Irremediable injury" should include the destruction of the stratigraphy of a site, despite the availability of what appear to be substantially similar objects on the market. O'Keefe comments, "[a] general trade in unprovenanced objects from various sites in a country or countries of the same region may destroy any efforts to properly survey, date, and verify the development of national culture" (O'Keefe 2017: 169).

Implementation of Article 9 has proven to be controversial. The relevant CPIA provisions allow the President of the United States to impose import restrictions, following a request by another State Party, upon designated categories of archaeological and ethnological materials pursuant to either an emergency action (19 U.S.C. § 2603) or a bilateral agreement (or memorandum of understanding (MOU)) between the United States and the requesting State (19 U.S.C. § 2602).

These import restrictions apply to designated categories of archaeological or ethnological materials rather than to specific documented artifacts. The CPIA defines an archaeological object, in part, as an object of cultural significance that is at least 250 years old and is "normally discovered as a result of scientific excavation, clandestine or accidental digging, or exploration on land or under water" (19 U.S.C. § 2601(2)). An ethnological object is defined as "the product of a tribal or preindustrial society" that is "important to the cultural heritage of a people because of its distinctive characteristics, comparative rarity, or its contribution to the knowledge of the origins, development, or history of that people" (19 U.S.C. § 2601(2)).

The process for achieving a bilateral agreement is onerous and cumbersome. A State Party initiates the process by submitting a formal request to the United States through diplomatic channels with documentation that the four statutory criteria mandated by the CPIA for entering into a bilateral agreement are satisfied. The four statutory criteria (paraphrased) are that the cultural patrimony of the requesting State Party is in jeopardy due to looting; the requesting State Party has taken measures consistent with the 1970 UNESCO Convention to protect its cultural patrimony; other States are taking similar measures to restrict the import of those archaeological objects whose import the US would restrict; and the imposition of import restrictions "is consistent with the general interest

of the international community in the interchange of cultural property among nations for scientific, cultural, and educational purposes" (19 USC §2602 (a)(1)).

The request is reviewed by the Cultural Property Advisory Committee, which consists of members appointed by the President. The members represent the interests of museums and the public, are experts in the international trade, or are archaeologists or anthropologists. The Committee makes a recommendation to an Assistant Secretary in the State Department, who then determines whether the statutory criteria are satisfied and, if they are, negotiates the agreement. Agreements last for 5 years and must then be renewed, although they may be renewed an unlimited number of times. Even though there are statutory provisions for emergency actions, which obviate the need to negotiate an agreement, any State wishing to have import restrictions imposed on an emergency basis must first request a bilateral agreement and submit the necessary supporting documentation (19 USC §2603). Import restrictions imposed in emergency situations can last a maximum of 8 years (an initial period of 5 years with one renewal period for 3 years), 19 U.S.C. § 2603(c)(3). As of mid-2018, the United States has bilateral agreements with 17 States: Belize, Bolivia, Bulgaria, Cambodia, China, Colombia, Cyprus, Egypt, El Salvador, Greece, Guatemala, Honduras, Italy, Libya, Mali, Nicaragua, and Peru. It also has emergency restrictions on the import of cultural materials from Iraq and Syria, pursuant to special legislation that implemented United Nations Security Council Resolutions 1483 (Iraq) and 2199 (Syria). This special legislation allows the emergency restrictions to last for an indefinite period of time.

The method of implementation used by both Switzerland and the United States has the drawback of not automatically applying to illegally exported cultural materials in the absence of a bilateral agreement. This means that in case of crisis situations, such as in Syria, both countries needed to take additional steps to prohibit import of illegally removed cultural materials. In the case of Switzerland, however, because the Swiss legislation allows the Federal Council to respond to crisis situations without need for a request from the affected State or negotiation of an agreement, import restrictions can be imposed on an emergency basis under the Swiss implementation of Article 9 of the 1970 UNESCO Convention. In the case of Syria, this is the route that was adopted when the Swiss Federal Council acted in late 2014 to restrict the import of cultural materials illegally exported from Syria after the beginning of the conflict in March of 2011 through its Order 946.231.172.7 (Switzerland 2014; Neuhaus 2015).

In contrast, it took an act of Congress to allow import restrictions to be imposed on the import of cultural materials from Iraq and Syria. In the case of Iraq, these import restrictions did not go into effect until 2008, although pre-existing trade sanctions prohibited import of cultural materials as well. Import restrictions on cultural materials from Syria went into effect in 2016, over a year after adoption of UNSCR 2199, which required all United Nations member States to enact such restrictions. This demonstrates the inefficiency of the United States' method of implementation of the 1970 UNESCO Convention and the necessity of revision to its legislation. In addition, the fact that the United States has bilateral agreements with only 17 States after 35 years as a State Party indicates that the process required by the CPIA is too onerous for both a requesting State and the United States to enter into and continuously renew agreements. While the agreements have been effective in limiting import of illegally exported archaeological objects from those 17 States, these represent only about 15% of all the States Parties to the 1970 UNESCO Convention. The US implementation of the 1970 UNESCO Convention is of limited effect with respect to the remaining 120 States Parties.

"Specific Designation": Japan

Japan has likely taken the most minimal approach to implementation of the 1970 UNESCO Convention among State Parties in that it restricts the import only of object that have been recorded or inventoried before theft or illegal export. This requirement is particularly problematic for regulating the trade in previously undocumented

objects, specifically, archaeological artifacts and ethnological materials. It is likely that Japan adopted this approach because Japan itself maintains inventories of cultural objects and otherwise allows free trade in objects that are not inventoried.

Japan became a party to the Convention in 2002 and enacted the Law concerning Controls on the Illicit Export and Import of Cultural Property (O'Keefe 2017: 204). Despite its name, it implements exclusively Article 7(b) of the Convention. Article 2 defines as cultural property what each State Party designates in accordance with Article 1 of the 1970 UNESCO Convention and thus seems to give the Convention a broad interpretation (O'Keefe 2017: 204–205). This is negated, however, in that Articles 3 and 4 apply only to "specified foreign cultural property" defined as "cultural property that has been stolen from an institution stipulated in Article 7(b)(i) of the Convention." Japan's implementation therefore seems entirely inadequate to deal with the problem of looted and therefore undocumented archaeological and ethnographic objects, as well as with the realities of difficulties in providing lists of objects stolen from museums and other public collections. (O'Keefe 2017: 205; Lee 2004: 12–13). While inventorying is a desirable goal as it reduces the incentive for theft and increases the likelihood of recovery, it is often not feasible to fully inventory all cultural objects.

Influence of the 1995 Unidroit Convention: Hybrid Approaches

Several market States have ratified both the 1970 UNESCO Convention and the 1995 Unidroit Convention. These States typically adopt comprehensive implementing legislation pursuant to both conventions. These measures emphasize compliance with the Unidroit Convention, which is mandatory in its requirements for implementation.

An example of a nation ratifying both conventions is New Zealand, which joined the 1995 Unidroit Convention in late 2006 and the 1970 UNESCO Convention in early 2007. Its comprehensive legislation, the Protected Objects Act, as revised 2007 (Public Act 1975 No 41), incorporates elements of both conventions into its domestic law. In addition to regulating the export of protected cultural objects from New Zealand, the legislation reflects Article 3 of the 1970 Convention in prohibiting the import into New Zealand of unlawfully exported protected foreign objects (Section 10A). The definition of "protected foreign object" tracks the definition of cultural property used in both conventions (Section 2(1)). This legislation also allows reciprocating States to bring actions to recover stolen or illegally exported protected objects (Section 10B).

It should be noted that those States Parties that are also members of the European Union must enact legislation implementing the European Union provisions regulating the movement of cultural objects: Directive 2014/60/EU on the return of cultural objects unlawfully removed from the territory of a Member State (OJ L 159, 28.05.2014) and Regulation on the export of cultural goods, Council Regulation (EC) 116/2009 of 18 December 2008 on the export of cultural goods (OJ L 39 of 10.02.2009). Italy's Code of the Cultural and Landscape Heritage enacted in 2004 (Legislative Decree no. 42 of 22 January 2004, GU Suppl. to No. 45 of 24 February 2004) is an example of legislation implementing these European Union provisions, as well as both the 1970 UNESCO and the 1995 Unidroit Convention.

Some States have ratified only the 1970 UNESCO Convention but have incorporated some particular principle or measure from the Unidroit Convention in a hybrid approach. The provision most typically incorporated pertains to the status of illegally excavated or legally excavated but illegally withheld archaeological artifacts. The Netherlands and the United Kingdom are examples of this approach.

The Netherlands. The Netherlands took an explicit hybrid approach in its implementing legislation. The Explanatory Memorandum that accompanied enactment of the Netherlands' legislation makes clear that it was influenced by various aspects of the 1995 UNIDROIT Convention, including its emphasis on a private law approach (Netherlands 2007/2008: 2–3). The Netherlands implementation follows the reciprocal model in that it prohibits the import of any

cultural property which has been removed from the territory of a State Party and is in breach of the provisions adopted by that State Party, in accordance with the objectives of the 1970 UNESCO Convention in respect of the export of cultural property from that State Party or the transfer of ownership of cultural property (Act of 9 December 2015, Relating to the Combining and Amendment of Rules Regarding Cultural Heritage (Heritage Act) section 6.3.1.)

However, the legislation goes a step further in also prohibiting the import of cultural property that "has been unlawfully appropriated in a State Party" (Section 6.3.2). The Explanatory Memorandum clarifies that unlawful appropriation includes "unlawful excavation at archaeological sites" and explicitly references the 1995 UNIDROIT Convention's equation of unlawful excavation with theft (Netherlands 2007/2008: 16). Furthermore, this provision applies even without establishing that an export control has been violated.

United Kingdom. One can suggest that the United Kingdom has taken something of a hybrid approach as well, incorporating the misappropriation definition from the UNIDROIT Convention. When the United Kingdom ratified the 1970 UNESCO Convention, it originally took the position that it did not need to enact implementing legislation. However, in 2003, it enacted new criminal legislation, the Dealing in Cultural Objects (Offences) Act 2003, although this was not characterized as a direct means of implementing the 1970 UNESCO Convention. This Act created a new offense for dealing in "tainted cultural objects" (chapter 27). One commits this offense if he or she "dishonestly deals in a cultural object that is tainted, knowing or believing that the object is tainted" (Section 1, Subsection 1). The statute defines a "tainted object" under the following circumstances: "(2) A cultural object is tainted if, after the commencement of this Act- (a) a person removes the object in a case falling within subsection (4) or he excavates the object, and (b) the removal or excavation constitutes an offence" (Section 2, Subsection 2). Subsection 4 refers to objects removed from "a building or structure of historical, architectural or archaeological interest" or from an excavation. For purposes of the statute, it does not matter whether the excavation or removal took place in the United Kingdom or in another country or whether the law violated is a domestic or foreign law (Section 2, Subsection 3). These provisions are clearly influenced by Article 3(2) of the 1995 UNIDROIT Convention, and, to that extent, the UK legislation bears a similarity to the Dutch legislation implementing the 1970 UNESCO Convention. Although it was not enacted as a means of restricting the importation of cultural objects, the UK legislation has been used as a means of seizing "tainted objects" upon entry (Vigneron 2008: 262, 292–93, 295; Steel 2012).

Future Directions

It remains to be seen whether the UNIDROIT Convention will ultimately garner the same relatively widespread acceptance that the 1970 UNESCO Convention has. At the same time, the salient question is whether nations that have ratified the 1970 UNESCO Convention will take their obligations seriously enough so that the convention will have its intended impact on the incentives to trade in looted, stolen, or undocumented cultural objects. While most State Parties have resolved the problem of the "specific designation" designation requirement, with the exception of Japan, the problem of a reactive rather than proactive plagues the method of implementation adopted by the United States and, to a lesser extent, Switzerland. Given that the United States is generally considered home to the largest art market, its inability to respond quickly and effectively to crises of looting caused by armed conflict and natural disaster is a serious detriment to our ability to protect and preserve the world's cultural heritage. The experiences of the past 15 years, since the 2003 Gulf War, demonstrate that the United States needs to devise a more effective method of implementation of the 1970 UNESCO Convention. Not only does the number of ratifying States need to increase, but the ratifying States must continue to seek better methods for implementing and enforcing the convention so that it becomes a more effective tool in the preservation of the world's archaeological heritage.

UNESCO (1972) and Malta (1992) Conventions

Willem J. H. Willems
ICOMOS International Scientific Committee on Archaeological Heritage Management (ICAHM), Faculty of Archaeology, Leiden University, Leiden, Netherlands

Brief Definition of the Topic

In 1972, UNESCO adopted the *Convention Concerning the Protectionof the World Culturaland Natural Heritage*, a treaty that has become UNESCO's most widely accepted international instrument and was ratified by nearly all its member states. Its purpose is to encourage the identification, protection, and preservation of cultural and natural heritage around the world considered to be of outstanding value to humanity. The Convention (http://whc.unesco.org/) is administered by the World Heritage Committee which consists of 21 elected nations that are party to the Convention.

The Convention names formal advisory bodies to the WH Committee, of which ICOMOS, the International Council on Monuments and Sites, advises on cultural properties and advisor on natural sites is the World Conservation Union. ICOMOS is responsible for the evaluation of nominations of cultural properties made by States Parties against the criteria laid down by the WH Committee. In addition to the basic criterion of "outstanding universal value," as specified in the Convention, these relate to aspects of authenticity, management, and conservation.

World Heritage has become a source of prestige for states and cultural properties on the list are rather strongly biased toward architectural heritage. The list also has an imbalance in that most non-western countries are rather poorly represented. In recent years, attempts are made to remedy such issues. Apart from that, archaeological sites benefit most from a nation's participation in the WH Convention not because some archaeological sites may actually make it to the list, but because the vast majority of such sites, that will never make it to the list, may benefit from the obligations imposed by the treaty, especially article 5 that requests proper management of archaeological heritage.

The Malta Convention (http://conventions.coe.int/Treaty/en/Treaties/Html/143.htm) dates from 1992, when the Council of Europe adopted *European Convention on the Protection of the Archaeological Heritage* (*Revised*). The treaty has been ratified by almost all European countries and has become an important international standard.

The convention revises the Convention of London and was drafted as a result of the economic development in Europe in the 1960s and 1970s that caused massive destruction of archaeological resources (Willems 2007). The rescue archaeology in those days was unable to cope with the consequences of rapid spatial development and it was clear that to accomplish a better survival of archaeological resources, archaeology should become part of the planning process. After all, the expensive rescue operations were a direct result of a failure to do so. In addition, it was considered desirable that in the future some of those resources could be preserved in situ because their importance was recognized at an early stage. This changed rescue archaeology into preventive archaeology. Further, it had become an accepted principle to charge the developer with the cost of archaeological work resulting from the development. And finally, it was realized that the public needed to benefit more from the results of archaeological research that was conducted mostly in an academic setting. These are the central principles enshrined in the Convention.

UNESCO Declaration Concerning the Intentional Destruction of Cultural Heritage (2003)

Sebastián Green Martínez
Universidad de Buenos Aires, Buenos Aires, Argentina

Introduction

International law regulates the rights and obligations of subjects of international law, such as States, international organizations, and individuals. Cultural heritage is protected under international law by different treaties, such as the Convention for the Protection of Cultural Property in the Event of Armed Conflict (see Schipper's entry ▶ "Convention for the Protection of Cultural Property in the Event of Armed Conflict (1954)"), the Convention on the Means of Prohibiting and Preventing the Illicit Import, Export and Transfer of Ownership of Cultural Property (see O'Keefe's entry ▶ "Convention on the Means of Prohibiting and Preventing the Illicit Import, Export, and Transfer of Ownership of Cultural Property (1970)"), the Convention concerning the Protection of the World Cultural and Natural Heritage (see Labadi's entry ▶ "UNESCO World Heritage Convention (1972)"), or the Convention for the Safeguarding of the Intangible Cultural Heritage (see Blake's entry ▶ "Convention for the Safeguarding of Intangible Cultural Heritage (2003)"), among many others. These are all binding instruments that establish international rights and obligations (mainly directed to States) related to tangible and intangible cultural heritage.

Declarations have also been adopted on the same field. Some examples are the United Nations Declaration on the Rights of Indigenous Peoples (see Nichols' entry ▶ "United Nations Declaration on the Rights of Indigenous Peoples (2007)"),

the UNESCO Universal Declaration on Cultural Diversity and the instrument under study, the Declaration concerning the Intentional Destruction of Cultural Heritage (the "UNESCO Declaration 2003"), adopted on October 17, 2003 by consensus of the General Conference of the United Nations Educational, Scientific, and Cultural Organization ("UNESCO").

Definition

Declarations in international law are instruments that are designed not to be enforceable and are considered "soft law" (Murphy and Damrosch 2014). However, resolutions adopted by organs representative of the international community "may sometimes have normative value. They can, in certain circumstances, provide evidence important for establishing the existence of a rule or the emergence of an *opinio juris*. To establish whether this is true. . ., it is necessary to look at its content and the conditions of its adoption; it is also necessary to see whether an *opinio juris* exists as to its normative character" (International Court of Justice 1996). In other words, instruments like the Declaration are susceptible of providing evidence of a belief that its content must be carried out as a legal obligation (or the emergence of such belief) and, hence, to provide evidence of the existence of an international customary law rule.

The Declaration was originally conceived as a reaction to the destruction of the Buddhas of Bamiyan, in Afghanistan (see Bartsch's entry ▶ "Bamiyan Buddhas"). In that context, UNESCO's General Conference intended to send a strong message indicating that intentional destruction of cultural heritage is not to be tolerated. Although it is not clear whether this goal was actually achieved (see below "Key Issues/Current Debates"), the draft of the Declaration had three main purposes: to support existing international legal obligations of States and individuals toward cultural heritage, to prevent new acts of intentional destruction of cultural heritage through State cooperation and the adoption of domestic appropriate measures, and to invite States to join applicable international treaties (O'Keefe and Prott 2011). In this line, the Declaration as finally adopted presents a preamble where the General Conference, among other things, recalled the "tragic destruction of the Buddhas of Bamiyan that affected the international community as a whole" (see below "Historical Background"); expressed concern "about the growing number of acts of intentional destruction of cultural heritage"; made reference to international treaties applicable to cases of destruction of cultural heritage – such as the 1954 Hague Convention for the Protection of Cultural Property in the Event of Armed Conflict-; and referred to the development of customary international law "as also affirmed by the relevant case-law, related to the protection of cultural heritage in peacetime as well as in the event of armed conflict."

The scope of the Declaration is expressly limited to "intentional destruction" of cultural heritage (Article II.2). Although in principle it does not cover the protection of natural heritage (in contrast with the Convention concerning the Protection of the World Cultural and Natural Heritage), it expressly includes cases of destruction of "cultural heritage linked to a natural site" (Article II.1). This has been considered an improvement, since it suggests that culture and nature are intertwined (Bandeira Galindo 2008; Hladik 2004). Further, its scope expressly covers intentional destruction during peacetime (Article IV) and wartime (Article V), avoiding the so-called dichotomy between international humanitarian law and peacetime instruments (Hladik 2012). In this vein, the Declaration suggests different measures that States should adopt to combat intentional destruction of cultural heritage (Article III).

The Declaration addresses the conduct of both individuals and States. The Declaration makes it clear in its Article VI that an act of intentional destruction of cultural heritage conducted by a State or the omission by a State to "prohibit, prevent, stop, and punish any intentional destruction" would give place to international responsibility

(in which case, the international law of State responsibility for internationally wrongful acts would apply). It also reminds that "States should take all appropriate measures" to criminalize individuals who "commit, or order to be committed, acts of intentional destruction of cultural heritage of great importance for humanity" (Article VII). It is remarkable that both articles make it clear that it does not matter whether or not the intentionally destroyed piece of cultural heritage is inscribed on a list maintained by UNESCO or another international organization. This means that the relevant factor is that the piece must be of "great importance for humanity" (Articles VI and VII).

Further, the Declaration recognizes that States should cooperate among themselves and with UNESCO to achieve the protection of cultural heritage within their territories (Article VIII.1), while it also encourages States to cooperate with each other in criminal matters related to the intentional destruction of cultural heritage (Article VIII.2). It also declares that it is necessary to respect the international rules that criminalize the breaches of international human rights law and international humanitarian law – or laws of war – when related to intentional destruction of cultural heritage (Article IX). Finally, it provides that States should ensure the widest publication as possible of the Declaration (Article X).

Historical Background

The Buddhas of Bamiyan were destroyed by the Taliban regime in Afghanistan in 2001. The figures were not only unique monumental pieces of cultural and religious significance, they were artistically remarkable, since they presented an exceptional mixture of Central Asian, Indian, and Hellenistic influences (Wangkeo 2003). After the destruction, it has been suggested that the international community was incensed and wanted to mark its deep contempt against such acts of destruction (O'Keefe and Prott 2011). In December 2002, UNESCO organized an ad hoc meeting of experts that gave place to a first draft of the Declaration, which was submitted to UNESCO where it was subject to negotiations between its member States (Lenzerini 2003).

The destruction of the Buddhas was completely unprecedented. Scholars pointed out that its uniqueness stem from several rare circumstances: the destroyed pieces were located in Afghan territory and were considered part of that country's cultural heritage; the Taliban regime had decreed the destruction of any figure different from those allowed by that group; the destruction was planned and publicly announced; before the detonation of the statues, different sanctions had been adopted by the United Nations and the international community. The destruction was considered also a way of protesting against the pressure exercised by UNESCO's officials and the United Nations Secretary-General (Francioni and Lenzerini 2003; Goy 2005; Bandeira Galindo 2008).

These unique circumstances proved to be legally challenging for the international community. On March 2001, 2 years before the adoption of the Declaration, the United Nations General Assembly debate regarding the situation in Afghanistan showed that, although every delegation rejected the Taliban decree that ordered the destruction of the statues, virtually no State considered the destruction of the Buddhas a violation of international law. The Ukrainian delegation was the only one that, during that session, condemned the destruction of non-Islamic historic monuments as "a flagrant violation of international law" (United Nations General Assembly 2001a). In May of that year, the United Nations General Assembly adopted Resolution 55/243, "strongly call[ing] upon the Taliban to abide by their previous commitments to protect the cultural heritage" (United Nations General Assembly 2001b). In this line, it has been suggested that sanctions adopted against the Taliban at the time were essentially moral (Goy 2005).

Another challenge arose regarding the international legal rules that would potentially apply to that situation: international humanitarian law or international law applicable in peacetime. The former applies only during armed conflict and, consequently, a breach of international humanitarian law could not, in principle, take place during peacetime. Certain scholars argued that, since Afghanistan was going through a civil war, international humanitarian law applied (Francioni and Lenzerini 2003). However, others were of the

view that the destruction of the Buddhas was not related, in any way, to the armed conflict and, hence, would not have been governed by international humanitarian law (O'Keefe 2006).

In any case, the most significant conclusion about the aftermath of such a monumental destruction and the reactions that followed is that the international community universally condemned intentional destruction of cultural heritage and expressed unanimous concern (Wangkeo 2003; Lenzerini 2003). In this context, the Declaration played a paramount role giving normative form to the condemnation by the international community.

Key Issues/Current Debates

It could be argued that the Declaration had certain aspiration to support the existence or the emergence of a customary international law rule. Actually, its preamble expressly states that the General Conference was "[m]indful of the development of rules of customary international law as also affirmed by the relevant case-law, related to the protection of cultural heritage in peacetime as well as in the event of armed conflict." It does not seem that the Declaration lived up to such purpose (Lenzerini 2003; Green Martínez 2012). Despite the Declaration itself constitutes a non-enforceable instrument, the drafters of the Declaration apparently emphasized such character through the word "should." Provisions that required action by States under the Declaration are seemingly mere suggestions: during peacetime "States **should** take all appropriate measures. . ." (Article IV); during armed conflicts "States **should** take all appropriate measures. . ." (Article V); further, "States **should** take all appropriate measures. . ." to combat intentional destruction of cultural heritage (Article III.1–III.4). As a commentator pointed out, the term "should" "is totally unnecessary in a declaration of principles, since by its soft-law nature this kind of instrument is not capable of creating international obligations of binding character, and the frequency of its use in the Declaration on the intentional destruction of cultural heritage clearly demonstrates that the main preoccupation of most of the negotiators was to preserve their domestic interests rather than to produce an instrument having the effective scope of safeguarding a value belonging to the international community as a whole" (Lenzerini 2003). In this regard, it has been considered that "[t]he Declaration does not itself impose obligations on Member States of UNESCO. Its hortatory and thus not fundamentally norm-creating language is incapable of doing so, and the *travaux préparatoires* show that this was not the intention" (O'Keefe 2006). Otherwise, States would renounce to the possibility of destroying or even affecting cultural heritage within their territories.

Nevertheless, the Declaration portrays a clear and unanimous contempt toward intentional destruction of cultural heritage and that, by itself, might constitute a step forward toward the emergence of a customary rule of international law. This is particularly relevant if we take into consideration that, although international actors expect that host states will in principle protect their cultural property, it has been suggested that no customary norm has developed against destroying cultural heritage in peacetime (Wangkeo 2003). This can be evinced from the United Nations General Assembly's debate, in which only one State claimed that the destruction of the Buddhas entailed a breach of international law and United Nations General Assembly Resolution 55/243, which did not refer to an existing customary rule applicable to the Buddhas. The prohibition of intentional destruction of cultural heritage was subject to intense debate during the drafting of the Declaration (Vrdoljak 2007; Francioni and Lenzerini 2003), and, in that context, the Declaration can be conceived as a step forward (Lenzerini 2003; Green Martínez 2012). It is worth mentioning that in the years that followed, positive developments took place in the international legal arena (particularly in the field of human rights law) suggesting that a customary rule may have emerged.

International Perspectives

States seem to be reluctant to give up their sovereignty when it comes to the administration of cultural heritage within their territories. In other

words, States have preferred to retain the power to physically affect cultural heritage, if necessary. However, the Declaration is evidence of the unanimous consensus in the international community against intentional destruction of cultural heritage, regardless of who carries it out and where it happens. Although the document is not binding, it reaches a universal agreement on the standards that mankind aspires to regarding the protection of cultural heritage.

Future Directions

Since its adoption in 2003, the values behind the declaration have been consistently applied. In 2013 the International Court of Justice rendered a judgment in the case regarding the *interpretation of the 1962 Judgment in the Temple of Preah Vihear case.* There, the Court referred to the World Heritage Convention and affirmed that both parties to the dispute (Cambodia and Thailand) must cooperate with each other and with the international community to protect a world heritage site. Furthermore, the Court affirmed that under the World Heritage Convention, both States have the obligation not to take any intentional measures which might directly or indirectly damage world heritage (International Court of Justice 2013). Although no express reference is made to the Declaration, the judgment rendered by the Court clearly displays how the values recognized in the Declaration are interpreted and enforced through the application – in this case – of the World Heritage Convention.

Moreover, the interest of local communities and the international community as a whole in cultural heritage as expressed in the Declaration has also been considered a step forward. While commenting the case referred to, a scholar affirmed that the Declaration strengthened the idea that safeguarding cultural and spiritual heritage concerns both local communities and the humanity as whole (Chechi 2015).

Finally, the criminal dimension of the Declaration is also relevant today. The Declaration provides for individual and State responsibility, while it also calls on States to assume jurisdiction over crimes involving the intentional destruction of cultural heritage, making a relevant reference point in the field of cooperation and criminalization (Vrdoljak 2016). In this context, it is worth underscoring that, when the Declaration was adopted, the International Criminal Court (the "ICC") was giving its first steps. Currently, the Rome Statute of the ICC – which counts with 123 States parties – criminalizes international destruction of cultural heritage. Under Article 7, intentional destruction of cultural heritage can be considered a crime against humanity of persecution during both peacetime and wartime (Ehlert 2014), and, further, under Article 8 of the Statute, it is considered a war crime to "intentionally [direct] attacks against buildings dedicated to religion, education, art, science or charitable purposes, historic monuments, hospitals [...] provided they are not military objectives." On 27 September 2016, in the case *Prosecutor v. Ahmad Al Faqi Al Mahdi* – the first case in which a defendant pleaded guilty before the ICC – Mr. Al Mahdi was convicted to 9 years of imprisonment for the intentional destruction of Timbuktu in Northern Mali. The Declaration called on the international community to criminalize the intentional destruction of cultural heritage, and, in this context, the Rome Statute of the ICC means an enormous improvement toward the criminalization of intentional destruction of cultural heritage worldwide.

UNESCO World Heritage Convention (1972)

Sophia Labadi
School of European Culture and Languages, University of Kent, Canterbury/Kent, UK
University of Kent, Canterbury/Kent, UK

The Convention concerning the Protection of the World Cultural and Natural Heritage (better known as the World Heritage Convention) was adopted by UNESCO (the United Nations Educational, Scientific, and Cultural Organization) in November 1972. Its key feature, the World Heritage List, has become one of the most popular global programs on conservation, with 1073 sites on the List in 167 countries (as of October 2017). Despite its popularity, this legal instrument is still badly understood. This entry aims to explain the mechanisms to inscribe sites on the World Heritage List. It will then present the key issues facing this legal instrument. A final section will present the way forward for the full implementation of the World Heritage Convention.

The World Heritage Convention: Basics Mechanisms

Since the creation of UNESCO in 1945, a number of international campaigns had been organized for the conservation of iconic sites, the first of which was launched in 1959 on the Nubian monuments of Egypt, threatened by the construction of the Aswan Dam (Bandarin and Labadi 2007: 28). The Convention concerning the Protection of the World Cultural and Natural Heritage (henceforth World Heritage Convention or The Convention), adopted on 16 November 1972 by the General Conference of UNESCO, was conceived as a more permanent mechanism that could protect cultural and natural heritage sites deemed to be of "outstanding universal value." This text was also adopted, because uncontrolled development was becoming one of the most significant threats affecting heritage sites. This is clearly highlighted in the preamble of this convention which stresses:

> The cultural heritage and natural heritage are increasingly threatened with destruction not only by the traditional causes of decay, but also by changing social and economic conditions which aggravate the situation with even more formidable phenomena of damage and destruction. (UNESCO 1972)

The Convention is a legal intergovernmental instrument and aims to set up a system of collective protection of natural and cultural properties of outstanding universal value for present and future generations. It needs to be ratified by countries which subsequently become States Parties to the Convention. This instrument came into force in December 1975 when 20 nations had ratified it. States Parties are the key actor of this international system. While it is often wrongly believed that UNESCO decides which sites should be on the World Heritage List, in reality only States Parties have the power to nominate sites located on their territory for inscription on the List. Those that extend beyond national borders can be nominated as joint transboundary or transnational nominations by more than one country (Bandarin and Labadi 2007: 37). To be able to do so, States Parties first need to submit to UNESCO a tentative list, which can be compared to a "wish list" of sites they plan to nominate in the next 5–10 years. For instance, the tentative list of Iraq includes some of the key archaeological sites illustrating its place as the cradle of civilization, including Babylon, Nimrud, or the ancient city of Nineveh.

To nominate a site for inclusion on the World Heritage List, States Parties need to prepare and submit to UNESCO a nomination dossier. The Operational Guidelines for the Implementation of the World Heritage Convention provide information of the format and content of these dossiers, which should clearly identify the boundaries of the site, describe it, and justify its outstanding universal value, using one or more of the official criteria, also detailed in the Operational Guidelines (UNESCO 2015; see Table 1 for the list of criteria). Nomination dossiers should also detail the authenticity of the property according to the

UNESCO World Heritage Convention (1972), Table 1 Criteria for the assessment of outstanding universal value

(i) Represent a masterpiece of human creative genius
(ii) Exhibit an important interchange of human values, over a span of time or within a cultural area of the world, on developments in architecture or technology, monumental arts, town planning, or landscape design
(iii) Bear a unique or at least exceptional testimony to a cultural tradition or to a civilization which is living or which has disappeared
(iv) Be an outstanding example of a type of building, architectural or technological ensemble, or landscape which illustrates (a) significant stage(s) in human history
(v) Be an outstanding example of a traditional human settlement, land use, or sea use which is representative of a culture (or cultures) or human interaction with the environment especially when it has become vulnerable under the impact of irreversible change
(vi) Be directly or tangibly associated with events or living traditions, with ideas, or with beliefs, with artistic and literary works of outstanding universal significance (The Committee considers that this criterion should preferably be used in conjunction with other criteria.)
(vii) Contain superlative natural phenomena or areas of exceptional natural beauty and aesthetic importance
(viii) Be outstanding examples representing major stages of earth's history, including the record of life, significant ongoing geological processes in the development of landforms, or significant geomorphic or physiographic features
(ix) Be outstanding examples representing significant ongoing ecological and biological processes in the evolution and development of terrestrial, fresh water, coastal, and marine ecosystems and communities of plants and animals
(x) Contain the most important and significant natural habitats for in situ conservation of biological diversity, including those containing threatened species of outstanding universal value from the point of view of science or conservation

values of the site and the cultural context, as well as the conditions of integrity which measures the "wholeness and intactness of the heritage and its attributes" (UNESCO 2015, paragraph 88). Despite this condition, some sites have been able to be inscribed on the List after having been destroyed, as is the case with the now famous Buddhas of Bamiyan, inscribed in 2003. Nomination dossiers should also detail the different management and conservation principles in place to ensure that the outstanding universal value of the site will be preserved in the long term. In the early years of the implementation of the Convention, dossiers were only a few pages long. In the past 15 years, these dossiers have increased in complexity and length.

Once nomination dossiers have been drafted by States Parties, they need to be submitted to UNESCO World Heritage Centre, which acts as the Secretariat to the Committee. These dossiers are subsequently evaluated by one of the advisory bodies to the Committee: ICOMOS (International Council on Monuments and Sites) for cultural heritage sites and IUCN (International Union for the Conservation of Nature) for natural heritage sites. The so-called mixed sites that are sites with cultural and natural heritage values and some cultural landscapes are jointly evaluated by ICOMOS and IUCN. These two organizations prepare an evaluation for each site, based on the nomination, consultation with relevant experts, and on-site visit. Each evaluation contains a recommendation on whether the site should be inscribed on the World Heritage site, referred back to the State Party for additional information, or deferred, which means that a completely new nomination will need to be submitted. The hardest recommendation is "not to inscribe," as this nomination cannot be presented again, except in exceptional circumstances.

These evaluations are presented orally during the World Heritage Committee meeting, which takes place annually and is retransmitted live (past Committee meetings can still be watched on YouTube). The World Heritage Committee is composed of 21 elected States Parties, in respect of Article 8(1) of the World Heritage Convention. The Committee takes the final decisions on whether a site should be inscribed on the World Heritage List, referred back for additional information, deferred, or not inscribed. The discussions on the nominations are the highlight of the committee meeting and are well attended by the different delegations and national media, which report back on the national sites that have been inscribed. The other key functions of the Committee are to examine the state of conservation of World Heritage sites, to decide the properties to inscribe or remove from the List of World

Heritage in Danger, and to determine the uses of the World Heritage Fund. The Committee also decides which sites should be deleted from the World Heritage List. So far, only two sites have been deleted from the World Heritage List. The first is the Arabian Oryx Sanctuary, deleted from the List in 2007 because of Oman's decision to reduce the size of the protected area by 90%, with plans to proceed with hydrocarbon prospection which would have destroyed the value and integrity of the property. The second property deleted was the Dresden Elbe Valley in 2009 because of a four-lane bridge construction project within the boundaries of the property.

Current Debates and Continuing Issues

Continued Unbalances of the List

One of the major recurring problems of the World Heritage List is its geographical unbalance, despite programs, primarily the 1994 Global Strategy, that have aimed to address this issue. As of 2017, the List is still dominated by the Europe region, with 434 cultural sites, 62 natural sites, and 10 mixed sites, representing almost 50% of the whole List. In contrast, sites located in Africa and the Arab states combined do not even reach 20% [51 cultural sites, 37 natural sites, and 5 mixed sites (9%) are located in Africa and 74 cultural sites, 5 natural sites, and 3 mixed sites (8%) are located in the Arab states]. The European domination of the List has not really changed over the past 23 years. As of 1994 and 2004, 55% of all sites were located in Europe (Labadi 2005: 92). It is quite fair to conclude, considering these figures and lack of evolution, that one of the key aims of the Global Strategy, "to correct the imbalances of the list between regions of the world," has failed (UNESCO 1994), despite different measures set in place. It is true that the Latin American and Asia-Pacific regions have been able to adopt successfully, to a certain degree, the principles of the Convention. Yet, the system remains Eurocentric. This situation can be explained by the lack of adequate tools to monitor the implementation of the Global Strategy. While major efforts have been given to training in underrepresented regions, with programs such as AFRICA 2009, their results have been limited due to lack of stability of trained staff or stability of structures (Office of the External Auditor for UNESCO 2011: 35). In addition, it seems that the preparatory assistance from the World Heritage Fund has not been as effective as could have been expected. Only 28% of all the sites that have benefited from preparatory assistance since the adoption of the Global Strategy with a view to nomination were inscribed on the List. Most importantly, there has been no will on the part of European States Parties to reduce the number of nominations that they wanted to nominate or to assist parties with less resources or experience.

Despite this failure, other unbalances noted in the Global Strategy report have been redressed, to some extent. This is the case, for instance, for a better representation of types of monuments and periods. For instance, "The Architectural Work of Le Corbusier, an Outstanding Contribution to the Modern Movement" comprising 17 sites located in Argentina, Belgium, France, Germany, India, Japan, and Switzerland was inscribed on the List in 2016. A number of transboundary routes, reflecting the cooperative nature of the Convention, have also been inscribed, including the Qhapaq Ñan, Andean Road System, an extensive Inca communication, trade, and defense network of roads covering 30,000 km, located in Argentina, Bolivia, Chile, Columbia, Ecuador, and Peru. Despite this relative success, the additional following issues remain.

Intrinsic Values and Consequences

"Outstanding universal value," the central notion of the Convention, has also led to issues, as it is still too often considered as being intrinsic to sites, instead of being considered as extrinsic (Labadi 2013). Such an understanding of significance means that World Heritage sites are considered as having inherent values that reside in the physical fabric of their structures, features that do not change in time and that can thus be appreciated by all mankind equally, regardless of individuals' backgrounds or their geographical location. Considering values as intrinsic in this manner also means that values are detached from their own

changing history, the wider social and cultural environments that shape them, as well as the shifting and conflicting significance that can be given to them by different individuals. This excludes, de facto, the possibility of drawing a comprehensive statement of significance that would take into account wider sociocultural values and considerations – in particular, values attributed by the local communities associated with the property. This is a way of giving a veneer of objectivity to the process of selecting sites for World Heritage Listing, by insisting that sites can be valued the same way by everybody everywhere. However, this veneer of objectivity and this understanding of intrinsic values are slowly being chipped away, as reflected, for instance, in the comments made by the delegate of Lebanon during the discussions on the nomination of the Historic City of Yazd (Iran) for inscription on the World Heritage List, at the 2017 World Heritage Committee meeting. This delegate criticized ICOMOS for having provided conflicting views on this site in its evaluation. He further stated that "inscribing a site on the List is not a mathematical formula" and that ICOMOS could make the Committee be aware of its diverging opinions among its panel.

One of the unfortunate consequences of this situation of attempting to consider values as intrinsic is the exclusion of local communities from the nomination, inscription, and management of sites. The major efforts to recognize the essential role of local communities should not be underestimated, as exemplified, for instance, by the 2002 Budapest Declaration, the 2007 5th C added to the strategic objectives, or the different events organized as part of the celebrations of the 40th anniversary of the Convention. Yet, a number of official documents are rather ambivalent concerning community participation, confirming the exclusionary trend of a framework that considers values as inherent to heritage sites**.** This ambivalence can be noted in the official format of the nomination dossier that States Parties need to fill out when proposing sites for inclusion on the List. Since 1997, one of the direct references to the local population is made under a section entitled "Factors Affecting the Site," reflecting the fact that communities are still sometimes considered a threat to sites. These exclusionary trends can also be explained by the use made by governments of the World Heritage List, as a tool to communicate about national narratives and national identities. In this nationalist endeavor, narratives focus on the great men of history and their great and impressive deeds. These narratives, termed by Laurajane Smith the "authorised heritage discourse," contribute to disengaging local populations whose values do not fit within this narrative (2006).

These exclusionary trends already appeared during the early days of the international heritage conservation movement, as illustrated, for instance, by the Abu Simbel Temples in Egypt. These temples were moved in 1968 onto an artificial hill to protect them from being submerged after the construction of the Aswan High Dam. These monuments were subsequently inscribed on the World Heritage List in 1979, but only the physical remains have been preserved; the intangible links with the Nubians have been lost. Since then, examples abound of sites inscribed on the World Heritage List that excludes communities, from Petra in Jordan to the Mahabodhi Temple Complex at Bodh Gaya in India, which has been documented as having been "cleaned" of its street vendors, with some areas close to the temple made into fee-paying attractions targeted at wealthy visitors (Geary 2015: 51–52).

Gender Unbalance

Gender equality is a top priority of the United Nations and its specialized agencies. Gender equality concerns all aspects of the World Heritage Convention, as gender relations are infused throughout the implementation of this legal instrument, from the identification of heritage to its conservation and management and its interpretation. Research on the representation of gender in official nomination dossiers has revealed a clear marginalization of the references to women and a strong bias toward androcentric representations of the past and a focus on the great men of history (Labadi 2013; 78ff; Labadi in press). This strongly positions women at the margin of the text, history, and heritage and makes them

invisible, secondary, and forgettable. Worse, some references tend to be a vehicle for stereotypical personal characteristics of women, describing them as sentimental, hysterical, prone to making decisions based on emotion, and incapable of rational action. It could have been thought that this focus on the great men of history could have changed in recent years, especially since gender equality issues have been given major prominence at UN level. Yet, on the contrary, the focus on the great men of history has increased in the recent nomination dossiers. There are now entire dossiers focusing on great men and their deeds, as is the case with the serial nomination of "The Architectural Work of Le Corbusier" (France, Argentina, Belgium, Germany, India, Japan, and Switzerland), inscribed on the World Heritage List in 2016. This invisibility of women was reflected, until recently, in the experts from both ICOMOS and IUCN who undertook evaluation missions of nominated sites for inclusion on the World Heritage List. From 2006 to 2008, 70% of ICOMOS experts were men (Tabet 2010: 25); 33 men out of a total of 34 acted as IUCN evaluators for the period 2001–2004 (Cameron 2005: 8). No precise information has yet been published on how these unbalances have been rectified.

Unsustainable Development

An increasing number of World Heritage sites suffer from unsustainable growth, which have taken many forms, from major infrastructure or housing projects to problematic tourism development (Labadi 2015: 137–150; Labadi and Logan 2015: 1–20; Labadi Forthcoming). These unsustainable projects, in a number of cases, threaten the very values for which the site was inscribed on the World Heritage List in the first place. Luang Prabang in Laos is but one example. The town of Luang Prabang was inscribed on the World Heritage List in 1995 under criteria (ii), (iv), and (v) for the exceptional fusion of Lao traditional architecture and nineteenth- and twentieth-century European colonial style buildings; its diversity of religious buildings, vernacular constructions, and colonial buildings; and because it is remarkably well preserved. In the past few years, the Greater Mekong Subregion (GMS), made of Cambodia, China, Laos, Myanmar, Thailand, and Viet Nam, has increasingly affected the heritage-led development of Luang Prabang (Labadi 2017: 45–60). For more than two decades, this subregion has worked toward an integrated economic cooperation program, with assistance from the Asian Development Bank. Tourism has been identified as one of the flagship sectors for development by the GMS Economic Cooperation Program and infrastructure development recognized as the means to achieve tourism growth. This has led to the construction of a high-speed railway link to China, an improvement of the road from Luang Prabang to the Thai Border, as well as the upgrading and expansion of the city's current airport facilities, to ensure an increase in regional tourism, with the expectation that the number of arrivals by air to Luang Prabang will increase by 400% over the next 20 years. These major infrastructural developments have raised concerns that the heritage of Luang Prabang will get overexploited.

However, it is not only the built environment that gets exploited. Local communities and cultures are also too often negatively impacted by these unsustainable trends. When communities have been able to draw some economic benefits from World Heritage sites, primarily through tourism, unfortunately, their well-being has often been impacted, particularly in developing countries. It seems in particular that the spatiotemporal dislocations between the developed and developing world have been aggravated by the World Heritage label. This is what was recently referred by Italian writer Marco d'Eramo as UNESCO-cide (2014). This means that tourists are attracted by the prospect of seeing something different from what they have at home and, when in the developing world, are interested by an authentic experience, a space of difference, distant from modernity. The result is that these tourists, most of them originating from the Western world, behave as if they were in a zoo, taking pictures of local inhabitants or trying to visit their homes uninvited. The presentation of World Heritage sites as being authentic has tended to exacerbate

further these issues, especially since authenticity has been defined as an original and unchanged state of things. This understanding of authenticity reinforces this dichotomy between the developed and developing world and stereotypes associated with these categories, in particular the fact that developing countries have remained authentic, in other words that they are unchanged and backward and have not yet entered modernity.

The Way Forward: Policy on World Heritage and Sustainable Development

The unsustainable trends highlighted in the previous section are rather surprising, considering that a number of key ideas related to sustainability were reflected in the very text of the World Heritage Convention from 1972 (Labadi 2017: 47). This is particularly the case with the idea of intergenerational equality, presented in Article 4 of the Convention, which recognizes that heritage should be identified, protected, as well as transmitted to future generations. This idea echoes the definition from the Brundtland report that sustainable development is "Development that meets the needs of current generations without compromising the ability of future generations to meet their own needs" (WCED 1987: 45). However, these continuous unsustainable trends might reflect the lack of clear policies on the integration of sustainable development approaches into the convention mechanisms. Indeed, up until 2012, only declarations (e.g., the 2002 Budapest Declaration, the 2012 Kyoto Vision) or events (e.g., 40th Anniversary of the Convention in 2012 on the theme of "World Heritage and Sustainable Development: the Role of Local Communities") aimed to deal with the concept of sustainable development. At its 2012 session, the World Heritage Committee made a historic request for a "proposal for a policy on the integration of sustainable development into the processes of the World Heritage Convention" (UNESCO 2012). This is historic as it is the first time that the Committee asked to define tools and ways to ensure that sustainable development principles were integrated within the implementation of the Convention. This "Policy for the Integration of a Sustainable Development Perspective into the Processes of the World Heritage Convention," fully adopted by UNESCO in November 2015, can become a powerful tool to align the convention mechanisms with sustainable development principles.

This policy is structured on the four core pillars of sustainable development from the document "Realizing the Future We Want for All," adopted at the Rio + 20 Conference (UNCSD 2012: 1). This document focuses on four core dimensions of sustainable development: (1) inclusive social development (including respecting, protecting, and promoting human rights and indigenous people as well as achieving gender equality), (2) inclusive economic development, (3) environmental sustainability (including resilience to disasters and climate change), and (4) peace and security. The first pillar on "inclusive social development" calls States Parties to ensure that the nomination, conservation, and management of properties are based on the recognition of the principles of inclusion and equity, through the provision of opportunities for all and the reduction of social and economic inequalities. This is further detailed through recognizing the potential of World Heritage properties to enhance the quality of life and well-being of all stakeholders, particularly local communities. The section on "respecting, consulting, and involving indigenous people and local communities" requests the free, prior, and informed consent and effective participation of indigenous people, whenever relevant. The section on gender equality requests equal representation of both men and women within activities for the nomination, conservation, and management of World Heritage properties. It also requests that women and men benefit equally from economic opportunities at World Heritage sites.

The second pillar on "inclusive economic development" is also strongly oriented toward social responsibility through encouraging inclusive and equitable economic development that generates decent employment and income for local communities. In addition, this pillar encourages local

initiatives and entrepreneurship through the strengthening of educational programs and capacity building. While the policy encourages economic growth, employment, and poverty-reduction initiatives within World Heritage properties, it also establishes some limits as parameters for sustainability. It does so by reiterating decision 37COM7 of the World Heritage Committee which urges States Parties and leading industry stakeholders "to respect the "No-go" commitment by not permitting extractive activities within World Heritage properties and by making every effort to ensure that extractive companies located in their territory cause no damage to World Heritage properties, in line with Article 6 of the Convention" (UNESCO 2013). This no-go commitment has so far been signed by 22 of the world's leading mining companies, Shell and Total, as well as a number of financial companies, including Paribas, HSBC, and JP Morgan. This restriction and reference to the no-go commitment helps the section on economic dimension to be linked to and respect environmental protection.

The third pillar on "environmental sustainability" aims to protect biological and cultural diversity, and the ecosystem benefits through integrating their preservation within the conservation and management of World Heritage sites. This pillar also aims to promote the potential of World Heritage properties for reducing disaster risks and adaptation to climate change. Finally, this section aims to enhance preparedness for effective response and building-back-better in post-disaster recovery and reconstruction strategies within management systems and conservation practice for World Heritage properties.

A fourth pillar focuses on the potential of World Heritage properties to contribute to peace and security. This includes the potential of heritage properties to prevent conflicts through celebrating cultural diversity, difference, or shared histories as well as contributing to post-conflict reconstruction through its inclusion in appropriate programs and policies involving multiple stakeholders. This section also relates to the protection of heritage during conflicts by complying with existing international heritage instruments (e.g., 1954 Hague Convention).

Conclusion

The World Heritage Convention is the most popular legal text and program on the conservation and management of cultural and natural heritage sites. This chapter has detailed the basic principles for inscribing sites on the World Heritage List, particularly the key role played by States Parties, responsible for identifying and nominating properties. This first section has also clarified the role played by the World Heritage Committee and the advisory bodies. A second section has detailed the recurring issues with the implementation of this convention, including the geographical unbalance of the List, problematic since it gives the impression that sites of outstanding universal value are mostly located in Europe, perpetuating the false idea that Europe is culturally superior to the rest of the world. Another issue concerns the association of outstanding universal value with intrinsic value. Far from a semantic debate, this consideration has some grave consequences, primarily the exclusion of local communities from the identification of values as well as from the conservation and management of World Heritage sites. This text has also detailed the issues with the continuous gender unbalances within the implementation of the Convention, despite gender equality being the top priority of UNESCO. Finally, this entry has explained the increasing unsustainable development trends affecting World Heritage sites, e.g., infrastructure development, tourism, or housing projects.

The "Policy for the Integration of a Sustainable Development Perspective into the Processes of the World Heritage Convention," fully adopted by UNESCO in November 2015, has then been presented, as it can become a powerful tool to align the convention mechanisms with sustainable development principles and solve the issues highlighted. However, many challenges lay ahead for its full implementation. The first step will need to be the inclusion of its key principles in the Operational Guidelines; the second step will be for the Committee to adopt a number of programs on key issues covered in this policy. The final step will be, of course, to raise awareness of

the principles contained in this policy and of its implementation mechanisms.

UNESCO World Heritage List and "Imbalanced" Properties: An African Perspective

Kaingu Kalume Tinga
National Museums of Kenya, Malindi, Kilifi County, Kenya

Introduction

Many countries throughout the world possess rich diverse heritage resources; these are either cultural – humanity's construction and acquisition over millennia – or natural heritage. In many cases, the cultural heritage and natural heritage are intertwined, thus adding value to the heritage properties (Posey 1999). On realizing that both "the cultural heritage and the natural heritage are increasingly threatened with destruction not only by the traditional causes of decay, but also by

changing social and economic conditions which aggravate the situation with even more formidable phenomena of damage or destruction," the General Conference of the United Nations Educational, Scientific, and Cultural Organization meeting in Paris from 17 October to 21 November 1972, at its seventeenth session, decided and adopted that UNESCO and the international community would collaborate with every state party to safeguard the heritage from destruction (UNESCO World Heritage Convention 1972). In spite of the great strides made by some countries since declaration of the UNESCO World Heritage Convention and other conventions that followed thereafter, by 2005, almost 50 countries did not have any properties inscribed in the World Heritage List. According to current records, by 2010, 48 countries do not have properties inscribed in the World Heritage List (whc.unesco.org/uploads/activities/documents/activity). By implication, these countries' heritage might be increasingly endangered unless the respective state parties have taken drastic measures to safeguard them from complete destruction. This entry highlights the wide disparities on the UNESCO World Heritage List graphically demonstrating that Africa has the least number of properties; it also explores the causes behind this huge void and suggests ways which Africa could claim a major stake on the World Heritage List.

Definition

Article 4 of the World Heritage Convention clearly states that "Each State Party to this Convention recognizes that the duty of ensuring the identification, protection, conservation, presentation and transmission to future generations of the cultural and natural heritage referred to in Articles 1 and 2 and situated on its territory, belongs primarily to that State. It will do all it can to this end, to the utmost of its own resources and, where appropriate, with any international assistance and co-operation, in particular, financial, artistic, scientific and technical, which it may be able to obtain" (UNESCO World Heritage Convention 1972). In 2001, UNESCO adopted the Universal Declaration of Universal Cultural Diversity after members realized that the 1972 Convention was basically dealing with Western heritage that seemed to favor European and North American state parties (Leask 2006: 11–14). But even before 1994, the committee had established new criteria such as traditional knowledge systems, trade routes, (itineraries), and traditional industrial complexes. Principally this was a move toward more representivity in the listing of World Heritage properties, resultant to which many African and other Third World state parties had their heritage properties inscribed to the World Heritage List.

By 2005, UNESCO had identified World Heritage properties through geographical regions, namely, Africa, Arab States, Asia and the Pacific, Europe, and North America. The total number of properties inscribed in the World Heritage List that year was 836. The Africa region (sub-Saharan Africa excluding the Arab countries) had 65 properties, accounting for 7.78%. The Arab States (including the North African States of Morocco, Algeria, Libya, Tunisia, and Egypt) had a total of 64 properties constituting 7.66%, while Asia and the Pacific boasted of 165 properties comprising 19.74%; collectively Europe and North America had the highest number at 430 properties that accounted for 51.44%, and finally, Latin America and the Caribbean had a total of 112 properties inscribed in the World Heritage List. This accounted for 13.40%.

Key Issues/Current Debates

From the foregoing statistics, Europe and North America ranked the highest, followed by Asia and the Pacific, Latin America, Africa, and the Arab States in that order. But even within Europe and North America region, wide disparities were observed; of the 430 properties, Italy topped the bar with 40 properties, followed closely by Spain with 38 properties and France and Germany with 29 properties each. The United Kingdom and Northern Ireland had 26 properties each, the Russian Federation had 20, and the United States of America had 19. Greece had 16, Sweden and

Portugal had 13 properties apiece, while the Czech Republic and Canada had 12 properties each. The rest of the European countries had less than 10 properties; the least was Malta 3 and Ireland 2, and the Holy See, Ireland, and Iceland had 1 property each.

Out of the 165 properties that the Asia and Pacific region had, China ranked the highest with 31, India 26, Australia 16, and Japan 13 properties; Indonesia, Sri Lanka, Iran, and Republic of Korea had 7 properties each, while the rest had less than six properties. State parties like Afghanistan, Malaysia, Mongolia, Turkmenistan, and the Laos People's Republic had 2 properties each. The Solomon Islands and Cambodia were at the bottom of the bar with 1 property each.

In Latin America and the Caribbean, of the 112 properties, Belize, Paraguay, Haiti, El Salvador Nicaragua, Saint Kitts and Nevis, Saint Lucia, and Uruguay were at the bottom of the pool with a paltry 1 property each; Costa Rica, Honduras, and Dominica had 2 properties apiece. On the hand, Mexico topped the region with 24 properties, followed closely by Brazil with 17 properties, Peru 10, Cuba 8, and Argentina 7; the remaining State parties had between 6 and 3 properties.

Of the Africa region, Ethiopia and South Africa topped the bar with 7 properties apiece, Tanzania 6, Democratic Republic of the Congo (DRC) and Zimbabwe 5 each, and Senegal and Mali 4 each, while Kenya had 3; the rest had between 2 and 1 properties. It follows however that, in 2006, the World Heritage List included 830 properties with only 82 sites from Africa (an increase of 17 properties within a year), accounting to roughly 10% of the total World Heritage properties. The statistics were not very different in the two successive years, 2007 (851 properties: 660 cultural, 166 natural, and 25 mixed) and 2008 (878 properties: 679 cultural, 174 natural, and 25 mixed parties).

Out of the 29 properties inscribed during 2008 32nd session in Quebec, Canada, only 2 properties were from Africa – the Le Morne Cultural Landscape (Mauritius) and the Sacred Mijikenda Kayas which include 11 sites that were given one serial number (these were Kayas Mtswakara in Kauma, Gandini in Duruma, Fungo in Giriama; Kambe, Ribe, Jibana, and Kauma; Mudzimuvya, Bomu/Fimboni in Rabai). During the 33rd session held in Seville, Spain, in 2009, the World Heritage Convention added 13 new properties to the World Heritage List and lost one property; thus, the 2009 World Heritage List includes a total of 890 properties, out of which 689 are cultural, 176 natural, and 25 properties in 148 state parties. In the same year, the Ruins of Loropeni in Burkina Faso were the only property listed from Africa. We have observed a few exceptions in the above analysis; for instance, in sub-Saharan Africa, both Ethiopia and South Africa still rank high with 8 properties each, according to the 2010 World Heritage List. They are followed by Tanzania with 7 properties; the majority of state parties in this vast region have less than 5 properties. In fact, the majority of the Africa state parties fall with the 1–4 property brackets.

In Asia and the Pacific region, China, India, Australia, and Japan had 31, 26, 16, and 13, respectively; Indonesia, Sri Lanka, Iran, and Republic of Korea had 7 properties each, while the rest had less than six properties. Five years later, in 2010, the scenario was not very different: China had 36 properties, India 28, Australia 18, Japan 14, Republic of Korea 10, Sri Lanka 8, and Indonesia 7. The rest of the region's state parties have less than 5 properties.

As for Europe and North America, the high figures are still increasingly predominant. According to the 2010 records which consist of 911 properties, Italy still leads with 43(4.7%), followed by Spain 41(4.5%), France 35 (3.8%), Germany 33(3.6%), and the United Kingdom 28(3.0). The United States of America has 19 properties; Greece boasts of 17 (1.8%); and Canada, Poland, Portugal, and Sweden at 13 each (1.4%), while the Czech Republic prides itself of 12(1.3%). Both Belgium and Switzerland have 10 each (1.0%), Turkey 9, and Austria 8, while the remaining state parties within this region had between 7 and 1 properties as of July 2010 (Table 1).

The above statistics lead us to three big questions: Why do the Africa region, the Arab States, Asia and the Pacific, as well as the Latin America and the Caribbean regions have very few heritage

UNESCO World Heritage List and "Imbalanced" Properties: An African Perspective, Table 1 The number of World Heritage properties by region 2012. (Source: UNESCO)

Regions	Cultural	Natural	Mixed	Total	(%)	States parties with inscribed properties
Africa	47	35	4	86	9	32
Arab States	67	4	2	73	8	17
Asia and the Pacific	148	55	10	213[a]	22	32
Europe and North America	393	59	10	462[a]	48	50
Latin America and the Caribbean	90	35	3	128	13	26
Total	745	188	29	962	100	157

[a]The property "Uvs Nuur Basin" (Mongolia, Russian Federation) is a trans-regional property located in Europe and Asia and the Pacific region. It is counted here in the Asia and the Pacific region

properties inscribed to the prestigious World Heritage List? Indeed, why do China, India, Japan, and Australia (and to some extent, the Republic of Korea (Asia and Pacific region)); Mexico, Brazil, Argentina, and Cuba (Latin America and Caribbean region); and Iran, Egypt, and Morocco (Arab States region) have relatively more properties inscribed in the UNESCO World Heritage List than any other state parties in their respective regions? More interestingly – specific European and North American countries – notably, Italy, Spain, France, Germany, and the United Kingdom; the United States of America, Greece, Canada, Poland, and Portugal; and Sweden, the Czech Republic, Belgium, and Switzerland top the World Heritage List. Why is there such a discrepancy?

It should be understood that many countries have the will and commitment to safeguard their heritage for posterity but are hindered by lack of infrastructure especially the technical capacity and financial resources. Developed countries like those in the European and North American region not only have the political will and commitment but also the financial resources and abundant qualified professionals in the heritage sector with well-established networks. Their heritage legislation is always reviewed to be in tandem with global systems and developments.

On the contrary other regions, especially majority of the Third World countries, there are innumerable, glaring, and varied contributing factors key of which are listed herein below:

- The existence of outdated colonial legislation that is mostly biased toward tangible heritage associated with the aspects of archaeological, paleontological, aesthetic, scientific, and artistic values (Negri 2008: 7–10).
- Many African countries have not recognized the importance of intangible heritage properties at global levels, except for a few like Malawi and South Africa. The tangible heritage and intangible heritage are intertwined; the latter refers to heritage resources associated with a place and which are not expressed in fabric but in languages, songs, activities like music making and dancing, storytelling, memory, and routine; places of symbolic meanings; etc. (http://www.unesco.org/culture/ich/index.php?lg=en&pg=0ng0002). Thus, UNESCO adopted the Masterpieces of Oral and Intangible Heritage of Humanity following which this criterion was proclaimed in 2003. Hence, the *Gule Wamkulu* (the Great Dance) masquerade performances of Malawi were inscribed according to this criterion (http://www.unesco.org/culture/ich/RL/00142).
- Most African governments have different priorities like healthcare, education programs, poverty alleviation programs, and provision of clean water; hence, they give little or no concern to their country's heritage sector. "This lack of recognition and political goodwill to include culture in the mainstream developmental agenda has resulted in the culture not being included even the development cooperation programmes. This has of course resulted in

lost opportunities by not using cultural knowledge, to address serious national issues and projects on HIV/AIDS, and other health concerns, Education, Environment, Rural Development, etc. In addition many countries are losing large numbers of cultural heritage and property in terms of indigenous knowledge, sites, monuments, antiquities and cultural landscapes among others" (Abungu 2006: vi).

- Conservation policies are not integrated into sustainable government policy frameworks encompassing heritage management.
- Poor planning and management of heritage resources where sometimes heritage managers condone the destruction of the heritage they are obliged to protect.
- Heritage management very difficult owing to insufficient and professionally qualified human resources.
- Inadequate financial and infrastructure resources for effective management of heritage properties.
- Incomplete or nonexistent national heritage resource inventories (databases) from which the state party nomination dossier to the World Heritage List originates.
- Lack of networking among heritage professionals – no sharing of information, knowledge, and best practice.
- Traditional heritage conservation methods have not been fully acknowledged in Africa.
- Lack of community participatory mechanisms for involvement of local communities especially the youth in conservation and management planning processes.
- Lack of awareness: politicians, decision makers, and communities unaware of their roles in heritage conservation and management.
- Civil strife, terrorism, and political sabotage (e.g., Rwanda, DRC, Iraq, and Somalia; the recent burning of Kasubi Tombs in Uganda) (Eboreime 2008: 1–5).

As remedies to the African heritage problems, the converse of the above should suffice. Moreover, the Third World countries should produce heritage practitioners with local and global views, who appreciate the diversity and dynamism of heritage and are equipped with the tools to manage their resources. They must be professionals who appreciate that some heritage resources are nonrenewable by ingraining indigenous perceptions of heritage in the legislations, professionals who appreciate and contribute to the democratization of heritage in relation to access, ownership, management of institutions, and knowledge production. To manage the heritage holistically, the legislation must be inclusive of the communities who produced, used, and conserved those heritage resources.

Heritage management is a collective obligation including the corporate sector and not only the preserve for governments, national parks, or communities. The disadvantaged regions should also document and patent their indigenous knowledge systems as security against foreign appropriation: The Kenyan kiondo, a bag made from sisal or bark, and khanga (women's wrapper) which were appropriated by Japanese and British companies, respectively, are examples of African ineptitude. Like the Japanese and Koreans, Third World countries must appreciate and inscribe her griots (storytellers), poets, musicians, craftspeople, and prophets.

Recent and Ongoing Programs

There are notable developments in the Africa region that underscore the essence of training in the methodologies of heritage management. From 2000 to 2009, the AFRICA 2009 program ran the course on the Conservation of Immovable Cultural Heritage in Sub-Saharan Africa that alternated yearly between the Centre for Heritage Development in Africa (CHDA) in Mombasa, Kenya, for the Anglophone- and Lucophone-speaking countries and Benin for the Francophone speakers. However, the course succeeded in equipping participants with among others, tools for writing of Conservation Management Plans. There was therefore pertinent need to equip heritage practitioners on tools for nominating heritage properties. African professional soon realized that in spite of Africa's rich and diverse heritage resources, the Africa region has continuously been able to have the least number of properties (about 9%) on the prestigious World Heritage

List. Thus, in 2006, the UNESCO World Heritage Centre launched the African World Heritage Fund (AWHF) based in Johannesburg, South Africa.

Future Directions

The African World Heritage Fund (AWHF) was launched in 2006 to support African state parties to implement the UNESCO Convention on the protection of the World Cultural and Natural Heritage. Following its strategic plan 2008–2010 and in collaboration with World Heritage institutions and African state parties, the AWHF initiated a training course in 2010, on the development of nomination dossiers for World Heritage listing by African countries. As part of its objectives, AWHF put in place the training program to build up competence of African heritage professionals in the development of nomination dossiers and management plans required by the World Heritage Committee when considering sites for listing on the World Heritage List.

The objectives of the course were threefold:

1. To give competence to African natural and cultural heritage professionals thereby improving the quality of African nomination dossiers submitted to the World Heritage Committee
2. To increase the number and diversity of African heritage properties on the World Heritage List
3. To reinforce the network of heritage professionals working on African World Heritage sites

Since the inception of the African World Heritage Fund, several training sessions have been conducted in various parts of the African continent with encouraging results.

Conclusion

We have seen that since 1972, regional imbalances have existed in the inscription of heritage properties in the World Heritage List. This entry has raised some poignant issues pertaining to the "imbalanced" scenario where some regions have tens of properties inscribed while other regions are tottering on the margins. This entry pinpoints the challenges affecting the inscription, sustainability, and opportunities in their use, in a fast globalizing period. This entry analyzes some recent landmark developments which have seen more African properties inscribed as World Heritage properties. Despite this improvement, Africa must rise up to the challenges outlined here and fight not only to inscribe its rich heritage resources to the world map but also to maintain them professionally.

UNESCO's World Heritage List Process

Melissa F. Baird
Department of Anthropology, Stanford Archaeology Center, Stanford University, Stanford, CA, USA

Introduction

A number of international charters and conventions have been influential in shaping heritage legislation and policy. The leader in these is the United Nations Educational, Scientific and Cultural Organization, known as UNESCO, whose members work to protect and conserve cultural and natural heritage. This entry provides a brief historical background to the creation of the World Heritage list, discusses the nomination process for cultural heritage properties on the List, and describes the roles of the World Heritage Committee, the World Heritage Centre and the functions of the two of the three advisory bodies, the International Council on Monuments and sites (ICOMOS) and the International Union for the Conservation of Nature (IUCN), that are mandated through the Convention to provide evaluations to the World Heritage Committee. The International Centre for the Study of the Preservation and Restoration of Cultural Property (ICCROM), which advises the Committee on the conservation of cultural sites, is not discussed.

Key Issues/Current Debates/Future Directions/Examples

Background

International awareness about conservation issues can be traced to the Athens Charter for the Restoration of Historic Monuments, more commonly known as the Athens Charter. In 1931, the First International Congress of Architects and Technicians of Historic Monuments, under the patronage of the League of Nations, adopted the Athens Charter to provide measures to protect monuments, establish international organizational and advisory bodies, and develop legislation to protect historic sites. Although the Athens Charter would be revised, its influence continues by providing a model that shapes conservation and preservation policies in Western countries (Smith 2006).

The period after World War II was characterized by large-scale restorations of war-damaged cities and monuments and a concern for the protection of cultural property. These concerns were central to the Hague Convention of 1954, which resulted in the Convention for the Protection of Cultural Property in the Event of Armed Conflict in 1956. The preamble to the Hague Convention recognized that "cultural property has suffered grave damage during recent armed conflicts and that, by reason of the developments in the technique of warfare, it is in increasing danger of destruction" and required that State Parties work to reduce impacts of armed conflict on cultural heritage properties and prohibit vandalism, misappropriation, or theft (Article 4).

In 1964, the Second International Congress of Architects and Technicians of Historic Monuments met in Venice to rework the Athens Charter. The Congress, made up largely of European representatives, developed guidelines and policies to assist professionals in heritage conservation to "safeguard [monuments] for future generations" (Preamble). The central aim of what would be known as the Venice Charter was to conserve and restore these monuments "no less as works of art than as historical evidence" (Article 3). The Charter reflected the shared and real concern of lost and damaged cultural patrimony and adopted measures to protect monuments. The ideas and values related to memory, identity, authenticity, and aesthetics became central to the ideology of how monuments were understood within the Charter.

The Venice Charter was part of a larger heritage preservation movement in Western countries

(the USA, Australia, countries in Western Europe) and became a guiding text to heritage practitioners (Smith 2006: 93). This conservation ethic, as well as an emphasis on materiality, physicality, universality, and aesthetics, would be readopted and refashioned in subsequent heritage legislation. The Charter also established a "fellowship" of practitioners and provided guidance on what was important to conserve (Smith 2006: 93). For example, ICOMOS, a nongovernmental organization of heritage practitioners founded in 1965 as a result of the Venice Charter, used the Charter to help guide decisions and train experts to undertake heritage work and site missions. ICOMOS will be further described in the next section.

Origins

The impetus for the World Heritage Convention can be traced back to the Athens and Venice charters and to UNESCO's attempt to protect heritage sites, the World Conservation Union (now known as IUCN) and ICOMOS lobbying, and US representatives pushing for an international natural and heritage convention. In the 1960s, UNESCO undertook large-scale projects to protect threatened heritage sites, such as the rescue campaign at Abu Simbel in Egypt, the ancient Nubian site that would be destroyed with the creation of the Aswan Dam. UNESCO also sponsored projects such as renovations at Mohenjo-Daro in Pakistan and Borobudur in Indonesia, and it was these types of interventions that led to discussions on guidelines and protection for international heritage sites (Turtinen 2000: 9). During this time, IUCN representatives were developing a global initiative to protect natural heritage sites and ICOMOS representatives were active in campaigns to protect cultural heritage sites. At this same time, US representatives were lobbying to create a World Heritage trust to preserve the most important cultural and natural sites in the world. Together, these international heritage bodies helped shepherd the creation of one convention to protect both cultural and natural heritage sites.

During its 17th session in 1972, the General Conference of UNESCO adopted the Convention Concerning the Protection of the World Cultural and Natural Heritage, also known as the World Heritage Convention. The Convention aimed to safeguard natural and cultural heritage and was developed by ICOMOS and IUCN, two of the three advisory bodies to the World Heritage Committee. The Convention, administered by the World Heritage Centre at UNESCO, is a "key legal instrument in heritage conservation" and has far-reaching influence and authority (Rössler 2006: 334). The Convention provides the legal framework and the administrative and financial support for the World Heritage list, an inventory of cultural and natural sites deemed of "universal" significance. As of May 2013 962 properties are listed; these include 745 cultural, 188 natural, and 29 mixed properties. Of these, 82 are designated as cultural landscapes, a category created in 1992.

The Convention also established the Intergovernmental Committee for the Protection of the Cultural and Natural Heritage of Outstanding Universal Value within UNESCO, called the World Heritage Committee. The Committee is composed of 21 States Parties to the Convention, elected at the annual General Conference. States Parties are responsible for nominating properties, providing a site management plan, and once a property is inscribed on the List, protecting the "World Heritage values" of the sites (Articles 4 and 6.2). Representatives for the States Parties work directly with members of the Secretariat at the World Heritage Centre in Paris, who provide feedback, oversee the preparation, format, and content of nominations, and ensure adherence to the rules and guidelines set in the *Operational Guidelines for the Implementation of the World Heritage Convention*, also known as the *Operational Guidelines*. The *Operational Guidelines* provide procedures for inscribing properties on the World Heritage list and List of World Heritage in Danger, protecting World Heritage properties, granting assistance under the World Heritage Fund, and mobilizing national and international support. The *Operational Guidelines* is an evolving document that reflects changes in scholarship and trends in heritage conservation and preservation, and the World Heritage Committee updates these frequently, based on recommendations from their advisory bodies.

Article 4 of the Convention requires that State Parties must ensure the "identification, protection, conservation, presentation, and transmission to future generations of the cultural and natural heritage referred to in Articles 1 and 2" (UNESCO World Heritage Convention). Cultural heritage, broadly defined, includes monuments, buildings, and sites, whereas natural heritage includes natural features or sites, and geological formations. The Convention emphasizes that properties must have "outstanding universal value" (Article 11.2) and meet conditions of "integrity and/or authenticity." Originally, the Convention presented two separate lists of criteria for nominated cultural and natural heritage sites. In 2004, members of the Sixth extraordinary session of the World Heritage Committee merged the two lists to require that properties meet at the minimum one of their ten selection criteria, which range from representations of "creative genius" to "containing. . .exceptional natural beauty and aesthetic importance."

Nominations to the World Heritage List

Countries who have signed the World Heritage Convention can submit nomination proposals to be considered for inclusion to the World Heritage list, and as of June 2010, 187 States Parties have signed. Figure 1 provides a model of the nomination process. As a first step, a State Party inventories their natural and cultural heritage sites, which are then included on the Tentative List and forwarded to the World Heritage Committee. To nominate a site to the List, the State Party selects a site from the Tentative List and prepares a nomination file to submit to the World Heritage Centre for review (Fig. 1). Once the nomination file has been completed and evaluated by the Secretariat, the nomination dossier is forwarded to the advisory bodies that are mandated by the World Heritage Convention to evaluate properties. The advisory bodies play a central role in how cultural patrimony is understood and represented. ICOMOS evaluates cultural and mixed sites and IUCN evaluates natural sites. Located in Paris, ICOMOS is an international, nongovernmental organization and network of heritage and conservation practitioners that advise on cultural properties and cultural landscape designations. IUCN comprises a large network of experts who evaluate and report on the conservation, protection, and management of natural heritage properties, and

UNESCO's World Heritage List Process, Fig. 1 The nomination process

develop strategies to conserve and protect the world's natural heritage and resources. IUCN plays a critical role in the World Heritage process and its members provide advisory services to the World Heritage Committee on nominations of properties with natural heritage values, provide evaluations of state of conservation of World Heritage properties, and train States Parties to identify potential properties. IUCN also advises ICOMOS on nominations for cultural landscapes.

Cultural heritage nomination evaluations involve a range of experts, including National and International committees, World Heritage advisory bodies, ICOMOS internal members, and in cases lacking adequate specialists, non-ICOMOS members. Once the "outstanding universal value" of the nominated sites is determined by ICOMOS, the advisory body calls on internal expert members to conduct a site mission (Fig. 2).

Members are also involved in national and international scientific committees established to provide guidance on cultural heritage issues. Today, 27 International Scientific Committees provide feedback to UNESCO on World Heritage Issues. ICOMOS committees serve as "technical bodies" and "undertake research, develop conservation theory, guidelines, and charters, and foster training for better heritage conservation, promote international exchange of scientific information and carry out common projects" (ICOMOS website). Members of the International Scientific Committee for Cultural Landscapes (IFLA), a joint committee between ICOMOS and the International Federation of Landscape Architects (IFLA), for example, advise ICOMOS on issues related to the cultural landscapes, including nominations of World Heritage sites.

Key Issues and Current Debates

Some of the key issues surrounding the World Heritage List are that it overrepresents western European properties, underrepresents the heritage of indigenous peoples, and disproportionately represents cultural and natural heritage properties (see Cleere 2001; Fowler 2004; Smith 2006). In 2000, former ICOMOS Director Henry Cleere found that over 55% of World Heritage properties

UNESCO's World Heritage List Process, Fig. 2 Overview of the ICOMOS evaluation process

were located in Western Europe (Cleere 2001: 25). In a study of representations and cultural diversity discourses related to World Heritage, Sophia Labadi (2007) argued that the World Heritage List lacked a diverse representation of minority groups and their values with little or no participation of local communities in the nomination process. Labadi (2007: 161) found that experts involved in these nominations stressed a very linear and conservative notion of history, as related to World Heritage sites, and that these narratives are flawed because they limit the perspectives and disallow competing claims and histories. The cultural landscape designation was created, in part, to address some of these imbalances; it was seen as a way to include non-Western landscapes and other cultural heritage properties that had been overlooked. Still, the majority of nominations to the World Heritage Committee are submitted by European countries and Europeans act as experts, work on World Heritage scientific advisory bodies, and provide recommendations to the Committee.

The criteria for nomination to the List, as defined, emphasize the universal values of a site. The concept of universality has been critiqued as creating a value system that promotes a specific and largely western and European cultural view of heritage (Cleere 2001; Smith 2006). More importantly, the notion that certain cultural properties are more valuable sets up a hierarchy and value system. Those monuments or sites from grand Western contexts are perceived to be inherently valuable, while those things from more modest contexts, presumably non-Western cultural contexts or less grand Western social contexts can, in certain circumstances, acquire or be acknowledged as valuable (Smith 2006: 90). It also creates a system that encourages a shared view of heritage, and emphasizes the scientific, aesthetic, material, and physical nature of heritage. Cleere (2001) argued that the criteria are purposely vague to allow for flexibility and inclusiveness, though Smith (2006: 97) disagreed and argued that the vagueness of the criteria in effect creates a set of assumptions about what constitutes "universal value" or "heritage."

In 2005, Christina Cameron, formerly a Chairperson of the World Heritage Committee, evaluated IUCN's World Heritage nominations and was critical of the process of developing and evaluating nominations, due to the lack of transparency. The sociopolitical contexts of heritage were explored by Baird (2009) in her study of World Heritage nominations (see also Bianchi and Bonicace 2002). She argued that World Heritage experts influenced and guided heritage outcomes and practices, and in some cases, adopted a possessive posture in heritage negotiations that excluded third party review and alternative interpretations. This critique of heritage experts had been argued before, and Smith (2006: 88) noted that many of the leading experts in conservation, preservation, and heritage fields give "political legitimacy" and influence policy-making decisions (Smith 2006: 88). As Smith (2006) reminds us, in addition to assessing World Heritage nomination dossiers, members write, edit, and lobby for national and international charters and conventions.

Numerous critiques of the impacts of tourism and development have emerged in the last decade (see, e.g., Harrison and Hitchcock 2005; Rakic and Chambers 2008). Much of the ideas of heritage are open to interpretation and often engage competing claims and negotiations. More importantly, as the former director of the World Heritage Centre, Francesco Bandarin (2005), noted the relationship between World Heritage sites and tourism is fraught with tensions. These tensions include issues of representation, authenticity, financial benefits, ideas of universal heritage, and competing claims, among others. One must recognize that World Heritage status increases international attention to the natural and cultural heritage resources within a property that can bring a suite of challenges, especially when these come into conflict with traditional owners' ideas of conservation and preservation or access to sacred lands. The distribution of local knowledge in international contexts must be addressed. The designation of a World Heritage status, whether explicit or not, assigns values and creates hierarchies of meaning.

UNIDROIT Convention on Stolen or Illegally Exported Cultural Objects (1995)

Patrick J. O'Keefe
School of Law, University of Queensland, Brisbane, QLD, Australia

Introduction

The UNIDROIT Convention on Stolen or Illegally Exported Cultural Objects 1995 came into force on 1 July 1998. As at 30 August 2019, it had 47 States Parties.

In 1983, a meeting of experts at UNESCO in Paris had recommended that UNESCO consult with another organization specializing in the harmonization of what are called "private law" issues, i.e., issues arising from dealings between private citizens. UNESCO already had the Convention on the Means of Prohibiting and Preventing the Illicit Import, Export and Transfer of Ownership of Cultural Property 1970 but this was a "public law" Convention which dealt with matters at an inter-State level. The experts in 1983 saw there were developing problems with matters such as time limitations (when would a claim for return of an object be barred because too much time had elapsed since the wrongdoing) and the status of the "bona fide" purchaser (a claim to an object could not succeed because the person who possessed it had bought it not knowing of any defect in the title).

UNESCO then asked UNIDROIT (International Institute for the Unification of Private Law) in Rome to take up the matter, providing seed money. Two studies were commissioned by UNIDROIT and meetings of experts invited in their individual capacities were held in Rome in 1988 and 1989. These were followed by four meetings of experts nominated by governments and, finally, a diplomatic conference in 1995. This history shows the length of time and the complexities involved in producing a convention dealing with cultural heritage when the rights of citizens are affected. That needs to be taken into account

when proposing new conventions or amendment of an existing one.

UNESCO was represented at all stages of negotiation of the UNIDROIT Convention. The two organizations collaborated closely and regard the 1970 Convention and the UNIDROIT Convention as compatible – as do others. For example, the Swiss Working Group on the International Transfer of Cultural Objects stated:

> The two conventions function independently but supplement each other by achieving a common purpose with different means. Therefore they are complementary. (Swiss Working Group 1999)

Definition

The UNIDROIT Convention deals with "cultural objects" (Article 2). This phrase was a conscious choice to avoid what some saw as the emotional content of "cultural heritage" and others the legal implications inherent in "cultural property." The objects are those which, "on religious or secular grounds, are of importance to archaeology, prehistory, history, literature, art or science," and they must belong to one of the categories set out in Annex A to the Convention. These include products of archaeological excavations whether regular or clandestine; elements of dismembered historical monuments or archaeological sites and antiquities more than 100 years old. The categories are the same as those for the 1970 Convention (O'Keefe 2017: 121).

Under Article 1, the Convention applies to claims of an "international character." This is not defined but clearly means that an international element must be involved. What precisely is needed to bring a situation within the definition would depend on the relevant facts. The claim must be for restitution or return of either stolen or illegally exported cultural objects.

The Convention does not apply to objects exported during the lifetime of the person who created it and for 50 years after the death of that person (Article 7(1)(b)). This ties in with the period of copyright as it existed at the time the Convention was drafted. It was felt that the creator of a cultural object had the right to export it if he or she so desired and thus earn a living from the work. The free sale of a person's creative work acts as an encouragement for future work. The lifetime exception does not apply to objects made by a member of a tribe or indigenous community for traditional or ritual use by that community.

Key Issues: Theft

Theft of cultural objects is the first issue raised by the Convention. The rule is blunt – if objects are stolen the possessor must return them (Article 3). States Parties are bound to implement this rule in their local legislation. It can then be relied on by private parties to claim back stolen objects.

The meaning of "stolen" is a matter for the law of the State where the claim is made. This can sometimes be difficult to establish. For example, in the case *United States v. Schultz* (178 F. Supp. 2d 45 (2002); 333 F.3d 393 (2003), at issue was whether the United States National Stolen Property Act applied. An English conservator – Tokeley-Parry – had arranged for some 2000 antiquities to be smuggled out of Egypt. A portion of these had been sent to Schultz – a prominent New York dealer – for sale through his network of contacts. Schultz was charged with conspiring to receive stolen antiquities that had been transported in foreign commerce in violation of the Act. The question was whether the antiquities were stolen and Schultz knew of this. The courts found against Schultz on both issues. The Federal judge at sentencing said that Schultz knew he was stealing "in every sense of the word" and was no different from "an ordinary thief" (Lufkin 2002: 5). Egypt had passed legislation declaring all antiquities were the property of the Government. This was actively enforced with the result that their removal from the country without permission meant they were stolen in terms of the United States Act (Gerstenblith 2003: 5).

Other States have claimed ownership of undiscovered antiquities with the objective of being able to claim them if they are clandestinely excavated and removed. The Convention supports this. Under Article 3(2), where a State has claimed

ownership, "a cultural object which has been unlawfully excavated or lawfully excavated but unlawfully retained shall be considered stolen." While the Convention provision has full legal force only among the 47 States Parties, it is also influential in arguments whether the ownership claims of other States should be enforced.

There are qualifications on the rule that stolen objects must be returned. Firstly, the abovementioned time limitations. The idea behind these is to have certainty of ownership. A person who claims to own an object should not be liable to have that claim disputed after a certain period of time has elapsed. This principle, in force in a number of legal systems, was hotly disputed during negotiation of the Convention. The compromise reached is quite complex, taking into account strongly held legal and political positions.

With time limitations, there are two factors to be considered – when does the time start to run and for how long. Under Article 3(3), the period begins "when the claimant knew the location of the cultural object and the identity of its possessor." This may be difficult to establish. Suppose the claimant is a State and one of its officials finds out where the object is held. Does that knowledge start the period running? What level within the administrative structure has to be reached before it does? Once the time starts running, the period is 3 years, but there is an overall period of 50 years from the time of the theft.

Fifty years is a relatively short time when the special character of cultural objects is taken into account. Consequently, a specific regime was created for objects "forming an integral part of an identified monument, or belonging to a public collection" (Article 3(4)). The limitation period is 3 years from the time the claimant knew the location of the objects and the identity of the possessor. There is no overall period unless a State, at the time of becoming party, makes a special provision in its law for 75 years or longer. It is not stated when this period should start but, considering the position of the rule in the text, this would seem to be from the time the claimant knew the location of the cultural object and the identity of its possessor. Where a State implements such an extended period for claims and an object from one of its monuments or public collections is found in another State Party, any claim to the material will be subject to a 75 year limitation period. Consequently, a State needs to carefully consider what it is doing if it opts to impose the 75 year limitation period.

The Convention specifically defines what is meant by a "public collection." This is a group of "inventoried or otherwise identified" objects. It has implications for those collections which do not have accurate inventories. A group implies that there must be more than one object, but there is no requirement of a unifying theme. The Collection must be owned by one of four types of organizations specified in Article 3(7)), including religious institutions in a Member State. Why these are specially singled out is not clear. It raises difficult practical questions. For example, many collections held by religious institutions are not inventoried; often they are not open to the public; sometimes part of the collection is owned by a religious body and part not. Can a person establish his or her own religion for the purpose of bringing the collection under this protection? (O'Keefe 2009: 398).

Singled out for specific treatment are sacred or communally important cultural objects belonging to or used by a tribal or indigenous community (Article 3(8)). Provided these are used traditionally or ritually, any claim for restitution is subject to the same time limitations that apply to public collections.

In returning a stolen cultural object, its possessor will, in many cases, suffer a loss, not only of the object but also what he or she paid for it. Should the successful claimant be required to pay compensation? This was, and still is, a controversial topic. However, the Convention makes provision for "fair and reasonable compensation" (Article 4). This will be decided by the courts where the claim is made. What is required to be taken into account is still debatable. For example, if the possessor has undertaken conservation, should the compensation include its cost and what of any increased value brought about by conservation?

There are two conditions that have to be met before compensation has to be paid. Firstly, the possessor must not have actually known that the object was stolen at the time of its acquisition nor can he or she have turned a blind eye to the circumstances surrounding the acquisition. In other words, if it can be shown that the possessor should have known from the facts at the time of acquisition that the object was stolen then no compensation will be payable.

Secondly, the possessor must prove that he or she exercised due diligence when acquiring the object. This is also a very controversial issue. In English law, the basic rule is that no-one can acquire a good title from a thief so there is no question of paying compensation to recover stolen property. However, if the object has been bought by a person who does not know it is stolen, a good title of ownership is obtained 6 years after the acquisition if no successful claim is made. The rule in the Convention is closer to that in what is known as the Civil Law, i.e., a system of law found in countries such as France. In those countries, a person obtains a good title if they bought the stolen object not knowing this and have kept it for a set period (e.g., 0–5 years depending on the jurisdiction) with no claim being made.

Requiring that due diligence be performed is one thing – establishing if it were adequate is another. For example, four Byzantine mosaics had been stolen from a church in Northern Cyprus and illegally taken out of the country. An art dealer called Goldberg bought them from a dealer called Dikman in the free port area of Geneva airport and took them to Indiana in the United States. They were claimed back by the Autocephalous Greek Orthodox Church of Cyprus. Goldberg testified in the American courts that, in an attempt to enquire into the right of Dikman to sell the mosaics, she had contacted the UNESCO office in Geneva (the main office is in Paris); the International Foundation for Art Research in New York (there was no record of her telephone call) and Customs offices in the United States, Switzerland, Germany, and Turkey (she could not remember the names of any person she spoke to and the Customs services had no documentation of any enquiries). On the other hand, she did not contact the Greek Orthodox Church nor either of the two administrations in Cyprus even though she knew that was where the mosaics originated. Her efforts were judged to be insufficient (*Autocephalous Greek Orthodox Church of Cyprus v. Goldberg* 717 F.Supp. 1374 (1989); 917 F.2d 278 (1990)).

In Article 4(4), the Convention provides guidance to a person intending to acquire a cultural object. For example, was the price too low compared to what a knowledgeable dealer or collector would expect? Were any databases of stolen objects accessed, e.g., the Art Loss Register in London or the list maintained by Interpol. Regard must be had to all the circumstances of the acquisition. In an American case, certain pre-Columbian artifacts were presented to a supposed purchaser (actually an FBI agent) "caked with mud and straw" (*United States v. McClain* 593 F.2d 658 (1979) at 663) – surely something to raise suspicions.

Key Issues: Illegal Export

There are some who argue that there is a qualitative difference between theft and illegal export of cultural objects. Others argue that both are morally reprehensible. These points of view were both represented in negotiations for the UNIDROIT Convention when the issue came up as to whether it should include provisions on illegal export as well as theft. Those who supported inclusion believed that there should be a more efficient method of obtaining return of an illegally exported object than that under the 1970 Convention. Eventually, there was agreement for inclusion of provisions on illegal export but the number of objects covered should be limited (Prott 1997: 52).

Article 5 commences with a general rule that a State Party may request the court of another State Party "to order the return of a cultural object illegally exported from the territory of the requesting State." This procedure simplifies return. Under the 1970 Convention, the request for return has to be dealt with on a State to State basis which is cumbersome. The requesting State, if it is the owner of the object, can also sue in the courts of the other

State for theft or try to have any export prohibition enforced. In either case, it has no special standing.

Under Article 5(3), the State can make its request to the court and the court must order its return if the requesting State proves that the removal of the object from its territory significantly impaired one or more of the following interests:

a. The physical preservation of the object or of its context
b. The integrity of a complex object
c. The preservation of information of, for example, a scientific or historical character
d. The traditional or ritual use of the object by a tribal or indigenous community

Then there is a much more general interest, namely, that "the object is of significant cultural importance for the requesting State."

Article 5(3) provoked a virulent reaction from some dealer, collector, and museum groups. Allegations were made that courts would be obliged to order the return of what a State demanded (Lalive 1999) and that museums would be emptied. Such persons did not credit the courts with the power and integrity to make decisions based on the facts. The procedure is streamlined but the State still has to prove that the removal impairs the interests listed and produce evidence to this effect. It is then for the courts to decide whether that is indeed the case.

Limitation periods apply. These are 3 years from the time the location of the object and the identity of its possessor was known. There is a maximum period of 50 years from the date of export.

The requesting State is required to pay compensation provided there is lack of knowledge of the illegal export on the part of the possessor of the same nature as for stolen objects. However, compensation is not required if the requesting State comes to an agreement with the possessor that he or she will retain ownership of the object (Article 6(3)). For example, the owner may find it desirable to lend the object to a museum in the requesting State. This could be acceptable to that State in that it avoids having to pay compensation and yet has the object available for public access. If the object was made by a member of a tribal or indigenous group for traditional or ritual use by that community, then it must be returned to that community (Article 7(2)).

It is common for objects to be sent from one State to another for perfectly legitimate reasons such as display in an exhibition. Often these are accompanied by an export permit which imposes penalties for failure to observe conditions. The Convention states that where there has been a temporary export, and the object is not returned within any time limit imposed, then it is deemed to have been illegally exported (Article 5(2)). This can be very significant where political changes have raised issues of ownership and the person to whom the object should be returned is unclear.

Finally, States that have rules, or introduce rules, more favorable than those in the Convention for the return of stolen or illegally exported cultural objects are not prevented from relying on them by the UNIDROIT Convention (Article 9). This was inserted to make clear that States already giving greater protection to cultural objects should not have to cut down existing protection.

Future Directions

There are no proposals for amendment of this Convention.

Unilinear Evolution and Lineal Time: A Critique

Andrés G. Laguens
Museo de Antropología, Facultad de Filosofía y Humanidades, Universidad Nacional de Córdoba, Córdoba, Argentina

Introduction

Nineteenth century evolutionism brought about the crystallization of a set of ideas in various fields of the natural and social sciences. That was a time of many conceptual changes that not only placed humans in a higher position in the Universe – defying the preeminent Christian order and history – but also gave an explanation of this new order. Evolution became a principle used to understand the origins and changes through time of many realms of life, from the Universe to the history of Humankind, in steady and lineal processes of transformation from the simplest to the most complex. This established the idea of progress as improvement and as a general goal of existence on Earth, as well. Its impact is so evident that even today, original concepts of those times, such as "progress," "development," "change," or even "primitive," are commonly used. Several evolutionary concepts are still commonly integrated in the way many people understand and explain the world such as gradualism, complexity, adaptation, and natural selection. The concept of time is, particularly, one of most prevalent.

In archaeology, despite criticism and the apparent long abandonment of the objective and lineal idea of time, a similar temporal model underlies many current proposals, at different scales. Ontological assumptions about time, such as its irreversibility and flowing character, seems to be in line with the nineteenth century evolutionism.

Definition

The idea of time according to the classic concept of evolution was a natural and universal phenomenon, external to humans, homogeneous, linear, directional, and quantifiable. As a given dimension, as in all space and to all entities of the universe, time inexorably progressed steadily in a continuous flow. Over time, a more complex ways of living unfolded at different points in different parts of the world, which could be sequentially ordered (according to their increased complexity) in successive periods along a common past. This in turn was a demonstration of human progress. As they moved toward the present, progress became more rapid, as if time were accelerated.

The natural sciences as well as the anthropology and archaeology of the nineteenth century provided the empirical evidence for this. The material, biological, and cultural remains of other life forms found in the same areas inhabited or conquered by Europeans, in conjunction with the same (and strange) customs and other objects found from non-European peoples around the world, were considered as definite evolutionary proof. Material things were the fossilized evidence of the past and its progressive and accumulative changes, while customs were their living testimony. The European and recent North American history were both evidence of the acceleration of time.

For evolutionism, time was not a special concern and did not propose an original idea about it beyond the prevalent one of that era. It did, however, contribute to its consolidation as a concept. The prevailing traditional view was that of a

single linear progression: past, present, and future. Thus, a long-held conception of time and history as a long cumulative process was reaffirmed, where progressive complexity led humanity toward better and more complex forms. This was supposed to be a kind of natural fate, showing a single universal time (i.e., "natural" time) in a linear fashion from past to future.

In that process of change, the key resided in the formal differences and similarities, both in the tangible and intangible aspects of societies. With difference comes change (a basic principle of the sensory experience of how we perceive the passage of time). Since change can only occur in time and with time, differences are evidence of its passing, as well the actions of evolution, understood primarily as cumulative change. Similarities among different societies were used as indicators of the rate of evolution, as long as they highlighted "survivals" – such was the evolutionary term – the continuity in time of some ancient traits, at the same time they showed parallelism between societies far away in space and time. Thus, evolutionism established and fully enforced one of the underlying principles of archaeological thought: Material things contain time.

Evolutionism sought to unravel the laws of culture and humanity, as biology does with nature. The quintessential method to achieve this goal was through the use of comparison. Classification and management became its primary tools. Two more theoretical and methodological ideas brought about a basic foundation: uniformitarianism and analogy. The principle of uniformitarianism, where the laws of nature are valid for all times and places, is perhaps the clearest and most explicit expression – if not the only one – on the theory of the evolution of time in the classical writings. The present time as a key to understanding the past – the famous sentence by the nineteenth century geologist Charles Lyell – is the most accurate summary on the evolutionary procedure, together with its concept of temporality.

The classification of the diversity of human life in time and space, combined with the sorting criterion that says that everything evolves from the simplest form to the most complex, helped organize humanity and its history. Humankind came to be perceived as a single, abstract, and ecumenical entity; while its history, was understood as occurring in a single universal development. Humanity and its history reached its highest manifestation only in the lifestyle of the then prevalent Western industrial society. On a more specific level, each culture – past and present – represented some of the conditions or lifestyles known by humankind, from the simplest life forms – those in the wild – to the most complex – those found in civilized societies. Nevertheless, all of them were subject to the same possibilities of progress – although not necessarily following the same orderly progression at every stage – given the unity of origin of humankind and the universality of the laws of evolution.

In this regard, the nineteenth century evolutionism was always considered as unilinear: There is only one course for human history following a natural order for certain types of life, from the least to the most complex, developed in a homogeneously flowing time.

Current Debates

Since the early twentieth century, much criticism has been directed toward this evolutionary perspective. Franz Boas' anthropological criticism and his followers, as well as the criticism coming from the functionalism movement of the first half of the twentieth century, contributed to dismiss several of the evolutionary principles. This criticism had perhaps a bigger impact on cultural and social anthropology rather than on archaeology. Critics not only denied the unilinearity of a single human history, but also the use of the comparative and social typologies that geared toward a more generalizing and homogenizing perspective.

However, the linear concept of time was not the primary target of criticism. The development of new archaeological analytical techniques to recover past time and order cultures chronologically held basically the same concept of time as a linear homogeneous and quantifiable phenomenon. The traditional diffusionism, the cultural-historical school of thought (important in South

America in the first half of the twentieth century), and the North American cultural history also held a similar concept of time. These lines of thought deepened a practical and theoretical consequence not explicitly expressed as a principle in unilinear evolutionism: the spatialization of time (Fabian 1983). While for evolutionists formal differences were mainly time, both post- and anti-evolutionist archaeologists held a similar view in which similarities and differences in space became time. Physical horizontal space, or distance, was regarded as another form in the materialization of time. Greater formal differences and less complexity (compared with the European vision of the world) meant a greater temporal difference. Also, the higher the spatial distance, the greater is the elapse or temporary "difference" (such as in deep geological stratigraphy). Thus, the physical attributes of objects and their spatial relationships were endowed with a significant dimension that defined and indicated time. Objects and distances were understood as material clocks.

From anthropological practice, the conceptualization of spatial distance as time difference led to the denial of the contemporary of the Western world with other different life forms; though coetaneous, they were considered as living in another epoch. This is what Fabian (1983: 31, 32) very well characterized as allochronism of anthropology: "a persistent and systematic tendency to place the referent(s) of anthropology in a Time other than the present of the producer of the anthropological discourse."

With the same concept of time, but conceptually distinct in relation to the causes of change, it was no surprise that those theoretical lines grouped cultures in relative chronological schemes following a linear order. There, time was a uniform and objective, divided into equivalent units, but historically and culturally differentiated. The oldest life forms physically evolved further away from more developed centers. Although these life forms usually continue to live together, they eventually disappear from the chronological schemes and are replaced by other forms of life in the next unit of time, usually in another space. The societies from the oldest time periods – usually corresponding to hunter-gatherers –are located in areas very far from the most modern times – that of people with agriculture and pottery – without actually coexisting in the archaeological narrative, even though that was the case. The coexistence of more complex and late societies with those perceived as less developed is also denied in archaeology.

The revival of evolutionary thinking in the mid-twentieth century in the United States tried to reverse these forms of chrono-spatial schematization. Two scales of action for the evolution of a multilinear concept of time were proposed: synchronic and diachronic, where the uniform and linear passage of time would allow the cumulative change of societies. On the one hand, a general trend, that of humanity or culture as a human phenomenon, with the emergence of forms of increasingly complex organization, from stage to stage. On the other, specific developments of particular cultures in local areas, with variations in different adaptive forms, with high to low in a setting that could be contemporaneous (Sahlins and Service 1960).

The introduction of radiocarbon dating in the mid-twentieth century as a form of absolute dating helped reinforce previous linear conceptions of time. This dating method validated concepts of time that were already generally held both in evolution, and diffusionism and cultural history. This method was functionally consistent with their views on cultural change, as long as the assumptions of the radiocarbon method are based on the same temporal ontology: time as a natural and homogeneous flow. The notion of time was essentially the same. The difference was that now it was possible to know the *amount* of time separating the events (O'Brien and Lyman 2002). The *when* in the chronologies became a *how much* in absolute chronologies. But, in addition, this was also the most tangible and objective evidence that objects contain time and that it will depend on our technical abilities and theoretical techniques to recover it.

Multilinear evolutionism was criticized for bringing into play many pre-understandings that were subject to be debated by non-positivist perspectives. Criticism on this concept of time was very similar to that directed toward the unilinear

notion of evolution: its general cultural types, variability reduction, the direct use of ethnographic analogy, and its principles and explanation of change. But this new line in evolutionism started to hold a multiple and contextual view of time. While equally smooth and linear, and part of the same general process, time was not regarded anymore as a single entity, but as two (or more) simultaneous or superposed times entangled as branches stemming from a common tree of general evolution. There is a relative time, that of the specific evolution of the species (i.e., cultures), relative to their particular environmental and cultural contexts (Sahlins and Service 1960: 2–6). At the same time, there is an absolute time, general, usually sequential, a-historical, in which successive levels of increasing complexity and organizational integration progressively emerged at different stages. Time was starting to be better understood in terms of its length from a dual approach: that of human temporality and that of ecological temporality.

The first theoretical approach in which environmental time is introduced as another time intertwined with the human one originates from what is known as the French Annales school (a periodical journal in which the main articles written by a leading group of French historians were published after 1929). It was not until many years later that these articles were incorporated in archaeological thinking. Maurice Braudel (1966), the main mentor of this school, distinguished, within the constant flow of time, the overlapping of different rates or speeds, understood as layers and fragmentations of history. The main, or the longest rate of time, is the one that involves a slower processing and transformative evolution. It is the time of long-lived structures, continuous and steady over generations and with a long balance with nature, the one that has an almost imperceptible effect on the lives of humans.

This duration of a parsimonious flow is fragmented and changes pace in short-term time. On the one hand, there are those of an intermediate time, of dozens of years, a quarter or half a century long. Intermediate time is the duration of social, political, and economic conjectures. It is the structural history of groups and clusters. On the other hand, there is a short-term time, that of individuals, of everyday life, of events. These short durations are neither perceived nor subjective or social times. Although Braudel referred to them as temporalities, they are only paces of time, the speed of historical phenomena depending on the magnitude of the processes. This time is superimposed and, at the same time, develops simultaneously. It is a multiple time.

The multiple time and the relationship between different temporal scales and the material record were proposed as temporary perspectivism (see Bailey 2007). Time is a process and representation, in terms of its links to the present. This notion basically proposed an archaeological ontology of time: a form of objectification in which the time of phenomena (of varying and relative durations or periods) materializes differentially under different resolutions, in particular concrete forms. Objects and the archaeological record form a temporary and material palimpsest (an aggregate of materials, objects, and meanings accumulated, of different ages and differential duration, subject to transformation and partial preservation). The ways of relating to the times of phenomena define four temporary perspectives, which enable or constrain different questions, requiring different explanations and methodologies.

Two important aspects are hereby added: the multiplicity of times and its differential materiality. In addition, the fourth perspective of time introduces the subjective time: a socially situated perspective, from the observer as well as from the people of the past. This perspective is conditioned by symbolic representations and cognitive categories about time, specific to each social group. This is the elapsed time that is differentially sensed. It is not just a matter of time, but also a conceptual issue. Time is not only multiple but can also acquire meaningful cultural forms.

A different perspective on lived time and its materiality can be found in the New Archaeology (Processual Archaeology). Time was not, according to this school of thought, a problematic issue and did not contribute substantially to theoretical discussions. Due to its concerns about understanding how the world worked, and how

processes and systems functioned, in its beginnings, it gave priority to the reconstruction of the mechanisms of interaction over time trajectories. However, various processual archaeologies indirectly began to deal with time and its relationship to the different issues of change, such as the mechanisms of evolution, adaptation, training processes, behavior chains, etc. These were concerns that involved time as an intrinsic factor in the development of these changes.

In other cases, time was considered a variable and came into play at the individual level. For instance, the proposals about artifact design in relation to conservative or expedient technological strategies (Nelson 1991) involve individuals thinking and considering time. Whatever it is the case, either in conservation strategies where tools are prepared in advance to their use or in expediency where there is availability of raw material and time to manufacture tools at the place of use, both involve a rational individual that takes into account the use and allocation of time. Equally, the analyses of procurement areas, optimal foraging models, or of cost-benefit, for example, put into play other notions of time. In spite of being a lived and perceived time, it is not freed from a Western-European concept of time. Time is seen as homogeneous, chronometric, and capitalist: It is a valuable resource (a form of capital) and decisions are taken based on its administration. Anyhow, it is important that here other time scales were introduced: that of individuals and that of short-term processes, and even of events (such as those of the knapping of a lithic artifact or its use). Although evolution operates inexorably as time itself, at a smaller scale, there are possibilities for the human in handling time. Individuals are active against time, even if this lies outside the individual.

This conception of time is also implied in the idea of surplus production and in current models of domestication – the management of time of others, animals, and plants – as well as in the considerations on the use of deferred resources or the intensification of production, for example. Also in the proposals of social differentiation and forms of social reciprocity, redistribution of resources, construction and maintenance of power, or the exchange of gifts, an active management of short-term time is at stake as it involves the appropriation of time by a few other individuals.

In these cases, it is not always a materialized time that is locked in things, but a relational time. Things are not containers of time. They do not contain the flow of time and they are not material clocks. Time is not the frame for the development of activities. It is, actually, a superimposed time which comes into play in the interactions between people and things. Neither is necessarily a linear time, conventionally flowing (though it well may have a past and a future, as is the case with redistribution, for example).

The possibility of a relational time can also be found in other postprocessual theoretical proposals. This is not the same relational positivist time subject to manipulation, but a time that arises from the practices and the active involvement of individuals with the material and the world (Gosden 1994). It is the short time of individual practices in its active dimension, along with the subjective time of individuals and their practices, putting at stake in these acts a whole series of socially acquired and incorporated dispositions, social memories, more ways of perceiving and experiencing the duration. In short, as maintained by Elias (1984), it is a relational effect, or what he calls the effect of the put-in-relation. It is a multiplicity of times, overlapping, of various lengths. A time that can acquire multiple shapes, socially and historically situated. Social practices produce and structure time, and there will always be as many forms of time as types of practices (Gosden 1994: 122–126).

Thus, life is composed of many times: The time that it takes to produce a lithic artifact has implicitly several temporalities, such as the time of other future practices (immediate or delayed), in other chains of coordinated actions in networks, leading at the same time to previous longer lengths of time, such as the socialization of the craftsman, or the short period of his training, and the long duration of the social structures of society where that practice takes place. The subsequent movement of that artifact and its participation in other

practices, from its first use to its ending on the shelf of a museum, require other multiple times that need to be considered. Without losing its fluid quality and overall linearity, the time of practice links things, people, and time, and from there, it branches out throughout its development into a multitude of other forms of different times and varied additional temporalities. The biographical perspective of objects (Gosden and Marshall 1999), for example, is one of the ways in which the realization of time in objects acquires these multiple dimensions, following a linear accumulation of history.

There is another social dimension of the temporality of the practices that has to do with the construction of social identities and life cycles. Whether it is over the small scales of daily and personal habits, or through the broader ones of sacred times, social rituals, and other public times, meanings are created and reproduced (Gosden 1994: 136). Among them, meanings related to gender, age, and lifestyle (Gilchrist 1999: 80). These are practices that not only deal directly with gender, but also with other practices that may be embodied – such as certain work or food habits, or sacrifices. Undoubtedly, there is a linear time, that of the flow of life which is marked biologically in bodies, but also bodies materialize overlapping stories of various durations.

Other ways of understanding the relational temporalities between objects and people have recently been deepened by some authors. Bearing in mind the timing of things and people, both would find themselves trapped in complex entanglements of moving relations of mutual dependence of human with things, things with things, and objects with humans (Hodder 2012). These entanglements have an important temporal dimension, as the mutual dependence keeps people busy, caring, arranging, and interacting with things. Since humans and things live in different temporalities – the life of things can be much longer or shorter than that of humans – there is no direct linearity in the flow of time.

The past is also involved in these entanglements, in a nonlinear, discontinuous, and fragmented way. This can occur either via the materiality of historical things that persist, which appear and have incidence in the present, or well as long-duration processes, or as other entanglements at a given point in time which guides where actions can be directed in the future (Hodder 2012: 100). The mess of things and people covers multiple times, past and present, short and long term, and, in turn, mutually intertwined, in a combination of different temporalities. Time lies in things, in people, and in relationships. It is constantly flowing in a linear manner, although at different time frames.

Overall, nonlinear perspectives of time, although still trying to break with linearity, take the past as ubiquitous, almost homogeneous in its effect on the present. While they recognize the different forms of temporality, it is as if history acted as a rather fuzzy or blurry whole. Questions like "the past is here, now" or "practices update the past through present actions," reinforce an almost causal linearity between past and present. The prospect of a historical materiality acting in the present, as suggested by Hodder, integrating with the present, is a nonlinear dimension of the past. The past presents a heterogeneous continuity (Lucas 2005). Our conscience can only perceive time as a flow, thanks to the memory that holds what happened, the past, and relates it to the present, as when we hear a tune or watch a movie. These retentions may have different depths, that is, age, or duration. When they manifest in the present, they work as "echoes" of the past (Lucas 2005: 26). There is then not such a thing as a linearity of the past (or with the past), but fragments and discontinuities that differentially arrive in the present time.

The past, rather than a linear succession of events, can be understood as a network of connected events, unequally distant from each other and the present. Each past period of time is extremely heterogeneous, made of fragments of different pasts (Olivier 2004). In fact, we do not recover events from a linear past, but connections that developed over time and are embodied in objects as memories in the present and not as representations of past events. It is a way of thinking about the different presents that shaped the past, in multiform times, in another kind of actualism.

In short, we can say that the different conceptions of time managed to link different elements, creating different ways of understanding it. Many of the elements are different, with different results. Due to the diversity of analytical units and ontological assumptions, it is difficult to make a critical comparison, although the acceptance of a certain kind of linearity and its materiality in objects emerge as elements in common. This issue is therefore theoretically complex. Even in different kinds of time and temporalities, including even the nonlinear, the idea of flow remains constant. Perhaps mental structures limit the ways in which they can express the passage of time and archaeologists fail at separating their own experiences when analyzing time, in a sort of familiarity that naturalizes certain aspects of common sense. It may also happen that archaeology is still subject to a long duration of the linear conception of time, a vision materialized with modernity.

The materialization of time on objects is a strong assumption common to all archaeologies from even the start of unilinear evolutionism until today. It has, in fact, been effective for the building of knowledge and the recovery of time. Today it is enriched and complex due to the relational perspective, where not only materials carry time, but relationships build it and make it happen.

International Perspectives

The concepts of time in South American archaeology, in a broad and spatial temporal perspective, have followed the successive unilinear international intellectual traditions of from the nineteenth century evolutionism to the present time.

In the nineteenth century (in the academic world at least), a kind of generalized allochrony denied the coetaneity of the "other," ignoring the continuity of the archaeological past with the societies of the present. Time was linear, but local history was interrupted and discontinued by another linearity, that of the Western world since the Spanish conquest. In the formation of nation-states from the nineteenth century, this view was used to justify the territorial expansion into indigenous lands and to define sovereignty, justifying so-called civilization and its development (Piazzini Suárez 2006). Once more consolidated states and archaeology as a discipline, this kind of allochronic thinking facilitated the creation and ownership of the pre-colonial past as heritage and, later on, the definition of the subject of study of a universal archaeology concerned with the study of cultural diversity. This situation began to change after the 1970s with the development of a Latin American social archaeology. In recent decades, other theoretical positions have begun to accept that continuity and respect or incorporate other voices in professional practice. New critical positions also incorporate self-reflection on professional practice and on its relationship to other people, their pasts and their voices (Gnecco 1999).

Future Directions

The recent concepts of multitemporality and on the relational perspectives of time, coupled with new approaches in the social sciences, seem to open new directions in terms of thinking about time and its linearity. In general, there is an increasing concern in archaeology about the short time, almost eventful time, depending also on a more general interest in individuals and subjectivities. Although this archaeology will need other methodological tools in order to define absolute short time lapses. The accuracy of the current absolute chronology is inadequate for an archaeology of short duration or of subjective temporalities. Neither its theoretical assumptions are in accordance with the particularities of relatively short phenomena such as some events and practices.

Also the concerns with the recent past (or more appropriately contemporary past due to its relevance today) are opening new lines of inquiry and expansion of archaeology (González Ruibal et al. 2010), working with the archaeology of warfare, state terrorism, and the disappearance of persons, in continuity with the present.

Inquiries into other ontologies (Henare et al. 2007) are now being considered in the archaeological discipline. Though, in general, this is

done from the perspective of the material culture or from human and nonhuman relations, time acts as an ontological category and, from a multi-relational stand, is part of a larger whole. The inquiries relating to other ontologies may venture into other temporalities not yet considered.

The nonrepresentational perspectives in human geography are challenging the conceptions of events and the flow, discussing the performative efficacy of the former and debating how to think about change in a world that is constantly being formed on its social aspect. The events make permanent differences, constituting the present, but in a temporality exceeding it, that includes past and future, not as memory but as anticipation, experience, and synthesis of a temporal subject (Rose 2010: 346–347) To think about archaeological time in a nonrepresentational form may enable some further analysis on small scales of events and individuals.

Despite these perspectives more focused on the subjects and their temporalities, and their multiple relationships with things and with nonhumans in general, as well as in their mutual agency, however, they have not yet developed further the analyses of the agency of time in itself. This lack of consideration implies the idea of time as a frame or scene and of an external flow. Time could be another agent in the network of interactions or the entanglements of things and people, and not an emerging entity. To some extent, unilinear evolutionism and the idea of progressive change and the widespread conception of time as a flow that acts on things – making them look older, accumulating time, modifying the archaeological record – imbues certain power of action to time, although closer to the idea of cause. But it is different to think of time with a capacity of agency, as it is the current thinking from posthumanism in relation to things, nature or other humans, as coactors interacting in concrete socio-material relationships (Bastian 2009). The multiplicity of simultaneous times and durations may have their different kinds of agency, as well as relational time. Perhaps a perspective from agency may lead us to rethink its linearity or, on the contrary, help to search for an agency capacity in its inevitable flow and linearity.

United Kingdom: Archaeological Museums

Alison Sheridan
Department of Scottish History and Archaeology, National Museums Scotland, Edinburgh, Midlothian, UK

Introduction

Museums containing archaeological material in the United Kingdom are many and varied. They constitute the principal means by which people can gain direct experience of the past, and in terms of *global* footfall, they continue to rival football matches as a favorite venue for leisure activity. However, some museums are significantly more successful than others in attracting visitors, with figures for 2012 showing that the British Museum remains far away the most popular visitor attraction in the UK, with over 5.57 million visitors. Many of the smaller museums would count themselves fortunate to attract 10,000 visitors a year.

While there are many fine examples of UK archaeological museums that have been refurbished, or relocated to new premises, in the last decade as a result of funding by central or local Government and/or the Heritage Lottery Fund (e.g., Shetland Museum, Lerwick), many archaeological museums in the UK face serious problems, principally relating to shortage of funds. This crisis in the museum sector means that some museums are being forced to close or to reduce staffing and services. This issue is not limited to the UK but is widespread around the world, and the way in which it is handled relates to broader debates regarding the role and utility of culture in society.

Definition

An archaeological museum can be defined as an institution that possesses a collection of archaeological material – be it obtained locally,

regionally, nationally, or internationally – which it curates, displays, and makes accessible for the benefit of present and future generations. Many museums, especially the larger examples, also regard the undertaking of research into the collections (either by their own staff or by others, or both) and dissemination of information about the collections as a core responsibility. In many museums, archaeological material is just one of a range of collections that are held. In the UK, an Accreditation Scheme exists to uphold national standards of museum practice. It is administered by Arts Council England in partnership with CyMAL: Museum, Archives, Libraries Wales; Museums Galleries Scotland; and the Northern Ireland Museum Council. The benefits of achieving accredited status include the eligibility to bid for large grants. Various other recognition schemes exist, including the designation of certain collections as being of national importance; once again, these can assist a museum in securing grants.

The distinction between a museum and a heritage centre is a moot point. Heritage centres generally aim to present the history and archaeology of a particular location and need not necessarily achieve this using real archaeological objects; however, many heritage centres do include such material, and some have collections that are in store as well as being on display. For this reason, the text below will include some consideration of visitor centres. The absence of a legally binding definition of a museum means that some visitor attractions call themselves museums even if they do not possess the kind of material that is normally found in a museum.

Historical Background

There is a long history of collecting and displaying archaeological material in the United Kingdom, extending back at least as far as the seventeenth century. The Ashmolean Museum in Oxford grew out of an early seventeenth-century Cabinet of Curiosities; the British Museum was founded in 1753 and was initially based on the collections of Sir Hans Sloane; the archaeological collections of what is now called National Museums Scotland started to be amassed in 1781, by the Society of Antiquaries of Scotland; and the Hunterian Museum in the University of Glasgow was founded in 1807 and is Scotland's oldest public museum. There are now well over 200 museums, scattered across the United Kingdom, whose collections include archaeological material, whether it be from the UK or from further afield. These museums range in size from the massive (British Museum) to the tiny (e.g., the Findhorn Heritage Centre and Ice House, Moray), and the scope of their collections ranges from the worldwide (e.g., the British Museum and Victoria and Albert Museum) to the individual site or object (e.g., the Mary Rose Museum, Portsmouth). Some, including the university-based museums such as the formerly-named Marischal Museum in Aberdeen, are funded – directly or indirectly and wholly or partly – by central Government; some (e.g., the Royal Albert Memorial Museum & Art Gallery, Exeter) are funded by City Councils or Local Authorities; and many (such as Bute Museum) are independently resourced, and of those, some have virtually no source of income, depending on volunteers to remain open.

Regarding archaeological material found in the UK, the principal collections reside in the national museums of the constituent countries in London, Edinburgh, Belfast, and (until the displays are relocated to St Fagans National History Museum) Cardiff, although there is no National Museum of England as such; the British Museum, which fulfils that role, presents material from the whole of the UK. Certain regional and local museums contain significant collections. In southern England, these include the Wiltshire Heritage Museum in Devizes, the Salisbury and South Wiltshire Museum in Salisbury, and the Dorchester Museum in Dorset, which house important collections of prehistoric material from Wessex; the Royal Albert Memorial Museum, Exeter and the Royal Cornwall Museum, Truro, whose collections cover much of the southwest; and the Museum of London which, as its name suggests, focuses on material from London and environs. In northern England, the Hull and East Riding

Museum in Yorkshire houses the nationally significant Mortimer Collection of prehistoric and later finds from Mortimer's barrow diggings in the East Riding of Yorkshire, while the Weston Park Museum in Sheffield houses the similarly important Bateman Collection, from that antiquary's barrow diggings mostly in the Peak District. The Great North Museum in Newcastle upon Tyne houses the collections amassed by the Society of Antiquaries of Newcastle upon Tyne, principally from Northumberland and Durham, while the York Museum contains a fine collection of Roman material from the city, and Tullie House Museum in Carlisle holds some important finds from northwest England. In Scotland, the museum formerly known as Marischal Museum in Aberdeen possesses sizeable collection of human and artifactual remains from Aberdeenshire and surrounding areas; Kelvingrove Museum and the Hunterian Museum in Glasgow are strong on the archaeology of the west of Scotland; Orkney Museum in Kirkwall possesses a large amount of material from excavations in Orkney; and Shetland Museum in Lerwick has a fine collection of Shetland archaeological material. And in Sutherland, the private museum belonging to Lord Strathnaver at Dunrobin Castle contains, among other material, a good collection of Pictish stones. In Northern Ireland, the Armagh County Museum (which is a branch of National Museums Northern Ireland) holds some significant finds from the county.

Individual treasures are to be found in some of the smaller museums. For example, the Rotunda Museum in Scarborough has, since 1834, displayed Gristhorpe Man, a 1.78-m-tall Early Bronze Age man, along with the lid of his tree-trunk coffin and the grave goods that accompanied him; while the Roman Army Museum at Vindolanda on Hadrian's Wall, Northumberland, houses the best collection of Roman writing tablets from Britain; Dover Museum houses the magnificent Bronze Age Dover Boat; and the Lynn Museum in King's Lynn displays the enigmatic Early Bronze Age "Seahenge" monument, with its central upturned tree base. Not all archaeological collections are housed in museums, however. The Duke of Northumberland's collection at Alnwick Castle, for instance, includes local and non-local (including Irish) prehistoric material, while the Duke of Argyll's collection at Inveraray Castle includes a rare Late Bronze Age flesh hook, an Iron Age massive armlet, a Neolithic Alpine jadeitite axehead, and a jet spacer plate necklace. Small displays are also to be found in some libraries, as at Todmorden Library, West Yorkshire, where most finds from an Early Bronze Age cemetery at Blackheath Cross ended up. Sadly, many archaeological objects remain in private hands and are never, or only seldom, seen by the public. The Crosby Garrett Roman parade helmet, a metal detector find which Tullie House Museum was unable to secure when it was bought at auction for £2 million in 2010, was displayed in the Royal Academy's *Bronze* exhibition in 2012 but otherwise remains with its anonymous owner. Finds that pass through the Portable Antiquities Scheme in England and Wales and are returned to finders may be made available electronically by means of the Scheme's database, http://finds.org.uk/database, although physical access to these finds (e.g., for research) is dependent on the goodwill of the possessor. Finally, considerable amounts of archaeological material currently reside with their excavators, awaiting a permanent home. The issue of storage is covered below.

Key Issues/Current Debates

The UK's archaeological material culture is therefore dispersed widely and in a dizzying array of institutions, facilities, and private hands. Leaving aside the issues relating to privately held material, what are the principal issues that relate to its curation, research, and accessibility?

By far the most serious problem is that of the shortage of resources which, as detailed below, has caused the closure of many museums and heritage centres, has led to cuts in staff and services, and has jeopardized the ability of many museums to acquire new material, to store adequately the material that they hold, and to make that material available for research. Added to this is an alarming managerial trend, in some quarters, towards regarding curators and conservators as an

expensive and anachronistic luxury that can be dispensed with.

The current crisis in museum funding is nothing new: museums have come and gone in large numbers over the last 150 years. However, the current economic climate is particularly harsh, especially for Local Authority-run museums where the culture budget was cut by 7.8% in 2011–2012. According to a recent report in the *Museums Journal*, 42 museums, galleries and heritage sites (including some containing archaeological material) have closed during the decade 2002–2012, with 30 of these closures occurring in the 2 years between 2010 and 2012 (Steel 2012). Financial cuts and the generally tough financial climate also mean a diminution in the staffing of museums and, in particular, in curatorial and conservation posts; for example, the trustees of Salisbury and South Wiltshire Museum were forced to take the decision to delete the Collections Manager/Curator of Archaeology post in 2012, while Museums Sheffield announced the loss of 45 jobs across its organization in February 2012 following the loss of £1.4 millions' support from Arts Council England and is facing another round of cuts in 2013. (Museums Sheffield advertised for a Curator of Archaeology in November 2012, but this post was to run only until the end of March 2015.) National museums are not immune from financial cuts, with all the UK national museums suffering significant reductions in their grant-in-aid. National Museum Wales has recently (February 2013) announced that 35 posts will be axed in the current round of restructuring, while others are downgraded (*Museums Journal* February 2013), and National Museums Northern Ireland still lack archaeological curators for their nationally significant collections held at the Ulster Museum.

The problems surrounding the acquisition and storage of archaeological material have been highlighted in the Society of Museum Archaeologists' report, *Archaeological Archives and Museums 2012* (http://www.socmusarch.org.uk/docs/Archaeological-archives-and-museums-2012.pdf), where it is pointed out that many museums have been forced to close their doors to new acquisitions and some 9,000 archaeological archives in England remain "undepositable." A similar situation (albeit smaller in scale) exists in Scotland, where an increasing amount of material that passes through the Treasure Trove system for allocation has no bidders. While the potential solutions to such a problem include the building of regional repositories, such a move would require collaboration between cash-strapped Local Authorities, or else private sponsorship, which is currently hard to secure. Nationalization of the national archaeological archive, which is the case in the Republic of Ireland, is most unlikely to occur.

The impact of the financial crisis on research into archaeological material in UK museums is becoming increasingly severe. Some museums (including Museums Sheffield: Weston Park) have closed their archaeological collections to researchers, while others limit the time that researchers can spend (e.g., at Hull & East Riding Museum) and/or charge them for access (e.g., Dorchester Museum and Salisbury & South Wiltshire Museum). While these measures may be understandable in terms of the need to budget staff time, they are having a significantly deleterious effect on archaeological research, particularly as undertaken by students. Research on large assemblages, which takes a considerable amount of time, is simply being rendered impossible in some museums. Furthermore, the fact that only a small percentage of those who care for archaeological collections are trained archaeologists and, of the latter, only a few are actively engaged in research means that much of the potential of the collections is not currently being realized. Just as research is adversely affected, so is the dissemination of information about the archaeological holdings, despite worthy initiatives such as Culture24 (formerly "the 24-hour museum," http://www.culture24.org.uk/home) and the proliferation of digitized catalogues, such as the online catalogues of the Hunterian Museum (http://www.huntsearch.gla.ac.uk/) and Wiltshire Heritage Museum (http://www.wiltshireheritage.org.uk/collections/).

This focus on the problems facing archaeological museums and other institutions holding archaeological collections in the UK is not intended to detract from the excellent work that continues to be undertaken by some museums. The phenomenal success of the British Museum's initiatives such as *The History of the World in 100 Objects* (http://www.bbc.co.uk/ahistoryoftheworld/) and of its *Ice Age Art* exhibition (7 February to 26 May 2013, http://www.britishmuseum.org/whats_on/exhibitions/ice_age_art.aspx) shows what can be achieved through tapping into the public's insatiable desire for archaeology. Similarly, the key role played by National Museums Scotland archaeological curators in the success of the Scottish Archaeological Research Framework (ScARF: http://www.scottishheritagehub.com/content/welcome) is widely acknowledged, and archaeological museum curators and conservators are playing an increasing role in the mass media dissemination of archaeological information, as shown for instance in the BBC series *A History of Ancient Britain* (http://www.bbc.co.uk/programmes/b010bg26) and in various web-based initiatives. Publications (both for the specialist audience and for the wider public) by archaeological museum curators and conservators continue to demonstrate that some museums – mainly, but not exclusively, the national museums in England, Wales, and Scotland – remain centres of excellence for archaeological research. This is because the individuals in question are uniquely placed to provide an overview and a depth and breadth of knowledge about archaeological material culture that cannot be matched by full-time excavators or by most university-based academics, who generally lack the in-depth knowledge of museum collections afforded to their museum-based colleagues. Finally, there are many splendid examples of recently refurbished museums (such as the Royal Albert Memorial Museum & Art Gallery, Exeter and The Collection in Lincoln).

As far as current debate within UK archaeological museums is concerned, most centres on the problems mentioned above. These problems eclipse concerns about ownership and repatriation – a topic which had previously set local museums against national museums and, increasingly, had involved local versus local museums and regional vs. regional museums in arguments over ownership. However, initiatives such as shared ownership and of proactive loan program (e.g., by the British Museum) have gone a long way to calming the debate, even though the politics of envy (directed against larger and better-resourced institutions) and competing claims for ownership or right of possession will probably always exist. One debate that tends to remain suppressed, due to fear over consequences, is that concerning the downward transformation in the status and power of curators in some museums over the past two to three decades, as museum management regimes that privilege other areas such as education, marketing, and collections management have tended to come to the fore.

International Perspectives

The problems and issues outlined above are by no means limited to the UK. Problems of resourcing face archaeological museums around the world, and the change in museum management philosophy that privileges other areas over curation and conservation has led to widespread cuts in the number of professionally trained curators and conservators in several continents. That said, there are still many excellent archaeological museums, and much world-class research is still carried out by museum curators and conservators. The funding model for archaeological museums may vary around the world, but – with a few notable exceptions – a general decline in public funding and a concomitant need to rely increasingly on charitable grants and commercially generated income can be discerned.

Future Directions

What of the future? The public's fascination with archaeology continues unabated, as is demonstrated by the crowds who have flocked to see parts of the (fairly) recently discovered

Staffordshire Hoard of Anglo-Saxon artifacts which are on display in Birmingham Museum & Art Gallery (until December 2014) and in the Potteries Museum, Stoke on Trent (until September 2013). Museums must continue to engage the public and maximize the accessibility of the collections while safeguarding their physical well-being for future generations. Advances in electronic technology mean that it is possible to deliver more, and more varied, information than hitherto, both within museum displays (e.g., through the use of applications for electronic media) and on the Internet. Much effort is currently being expended on developing increasingly sophisticated electronic means of access to collections and to the information about them; the challenge remains to ensure that the information that is disseminated by these media is correct, authoritative, and accessible but not dumbed down. There is also useful current research into haptic technology, to address issues surrounding the physical experience of museum objects. Such initiatives will benefit not only the visually impaired but all who wish to gain a sensation of touching an object that is protected in its glass case. Community engagement, through incorporating features such as Twitter, Facebook, and Flickr within a museum's range of communication media, is a rapidly growing area that is likely to continue to expand. By allowing the broader public to register their feelings and share ideas, reactions, and information, this constitutes a democratization of knowledge and an ethos of sharing that is in tune with the Zeitgeist (This should not, however, take the place of scholarship or of hard-won specialist knowledge.).

In UK archaeological museums, issues of storage and physical access to collections will require more creative and "joined-up, bigger picture" thinking than has been the case; the establishment of regional repositories, with facilities for research as well as for storage, would seem to be a sensible way to proceed. Inevitably, more museums will close and some may be forced into partnerships, and it is likely that, for their funding, many museums will have to rely increasingly on the Heritage Lottery Fund (and other charitable institutions) and on private and commercial sources. But the success of past initiatives such as *Renaissance in the Regions* – whereby nearly £300 million was spent on revitalizing certain museums in England between 2002 and 2011 and further monies were subsequently disbursed by Arts Council England under the Renaissance Major Grants Programme – shows just what can be achieved when the political will exists (http://webarchive.nationalarchives.gov.uk/*/http://www.mla.gov.uk/what/programmes/renaissance/renaissance_review_launch). UK archaeological museums find themselves at a time of particular stress and hardship and under increasing pressure to compete with other tourist attractions to deliver a crowd-pleasing "offer." Pulling off that particular trick while not losing sight of their core responsibilities to care for the collections in perpetuity, to research them and facilitate research by others, and to maximize accessibility is the challenge faced by museum directors throughout the UK.

United Kingdom: Cultural Heritage Management Education

Donald Henson
York, UK
Institute of Archaeology, University College London, London, UK

Introduction

Cultural heritage management depends on public goodwill as it is funded out of taxpayers' money or out of developers' money at the behest of government. Without education in heritage and archaeology there will be less awareness of the need to manage cultural heritage, and heritage organizations will struggle to gain public funding. Cultural heritage in the UK is managed by various organizations. There have long been museums, which originally were intended to be educational. There are national agencies in different parts of the Kingdom: English Heritage, Historic Scotland, Cadw (in Wales), and the Northern Ireland Environment Agency. These have ancient sites and remains in their care, and education about these sites is part of their work. In Scotland and Wales, there are also Royal Commissions on Ancient and Historic Monuments which also investigate cultural heritage. There is the National Trust, and the National Trust for Scotland, both independent of government and holding many landscapes and historic houses. Local government officials also record and conserve the local historic environment. There are charitable trusts and companies who carry out fieldwork. All these organizations carry out education, either through training or as public outreach programs. There are also some organizations and sites which have education as their main purpose. These include living history or experimental reconstruction centers, the Young Archaeologists' Club, and the education sections of museums which form a distinct professional sector. Of great importance in the UK is the role of the voluntary sector. They run independent museums of all kinds, and also heritage assets such as steam railways. These often work with schools.

It is important to understand the mind-set of the cultural heritage management profession. The remains of the past are seen as a resource for investigating the past. They are thought to be fragile, being eroded and destroyed every year, and so a precious resource that has to be conserved for future generations. The idea that remains of the past have to be conserved is dominant. Encouraging public access to these remains can be seen as a threat to their long-term survival. People erode sites by walking on them and damage artifacts by handling them. Recording and conserving remains is also the main objective of most heritage management organizations. Senior management in most organizations has come from a research, recording, and conservation background. Education is, therefore, not always welcome, and is often seen as a peripheral part of a service, poorly resourced, lacking trained staff, and the first to be cut when budgets are tight. The problems faced by education within museums were highlighted by David Anderson in his report *Common Wealth* in 1997 which argued for a higher profile and more resources for museum education. Much of what he said is applicable still within the wider cultural heritage sector, even if museums have made great strides in implementing Anderson's views.

Key Issues

Work with schools tends to be with primary schools and children aged 5–11. Schools and colleges do not usually offer courses in archaeology or in heritage, and neither is a subject in the various national curricula in the UK. Each of the four nations in the UK has its own education system with different curricula. England, Wales, and Northern Ireland share similar qualifications, while those of Scotland are rather different. There are formally laid down curriculum expectations, detailing the subject content to be taught up to the age of 14 or beyond. At 14–16, students will study for named qualifications in specific subjects: GCSEs in most of the UK and Standard Grade in

Scotland. At 16–18, they will study for AS and A Levels in specific subjects or Highers and Advanced Highers in Scotland. In school curricula, the subject most usually linked with cultural heritage in teaching is history.

However, archaeology does appear at AS and A Level, the qualifications taken at ages 17 and 18 upward. There used to be an Archaeology GCSE, taken at age 16, but this was abolished by its awarding body as being expensive to run for the number of students it attracted. There is both a shortage of teachers with a background in archaeology and a lack of awareness that archaeology is a very good academic subject with high standards of teaching and learning. Heritage can also be taught in a few vocational qualifications as part of leisure and tourism, but this is far from common. This is especially unfortunate when most of the history taught in the UK schools at the ages of 13 and over is modern history, modern being the twentieth century and its world wars. Pupils think that the past only consists of Hitler and Stalin, taught over and over again from the age of 13–18. There is one GCSE in history that explicitly includes heritage management and marketing alongside archaeology as options. This was created specifically to counter the modern history bias, but is not available to all the schools as it is restricted to only around 100 schools.

There are various barriers to good education work in the cultural heritage management sector. These are partly educational, partly archaeological. Among teachers, there is a lack of understanding about archaeology and its links with historic sites. Archaeology is seen simply as excavation, while historic sites are seen in the same light as museums – places that reflect a historical narrative. At best, they offer a story to be read and passively absorbed by pupils. Most teachers lack training in how to use historic sites and rely heavily on the education staff at such sites for ideas and expertise. They also often lack the detailed historical knowledge that would involve the site into its context. Curriculum content also acts to constrain which heritage sites will be used. If the site represents a period that is not taught in the curriculum, then it has to work harder to attract teachers' interest. The amount of curriculum time available for subjects like history is being squeezed by other subjects in secondary schools, where only one third of pupils study the subject at age 14+, and an increasing number are allowed to drop it at age 13. Issues of cost, health and safety, and curriculum time can make it hard for schools to organize trips to heritage sites.

Cultural heritage organizations usually need to subsidize their education work. It is not usually possible to cover all the costs by charging schools. Some organizations are unwilling to spend scarce money on education. In times of recession or spending cuts, education is often among the first casualties. Within the heritage profession, there are few employees with specialized training in heritage education. Some organizations like to employ former schoolteachers, yet the skills of a classroom teacher are different from those of a heritage educator. There are as yet few postgraduate courses in the UK that teach these skills. Within the cultural heritage sector, there can be a dominance of people with a research and conservation background, for whom education is at best a peripheral concern, and at worst an active distraction from the "real" business of cultural heritage management. Some organizations, therefore, choose not to carry out any education work.

In spite of these educational and archaeological barriers, there are also causes for optimism. Many archaeologists have a zeal for education and a commitment to help the public engage in cultural heritage. The Council for British Archaeology has done much to secure the place of heritage nationally within education. Many organizations that receive public funding realize that it is their duty to serve the people in return for this, and education is one of the key services. The nature of archaeology and heritage is ideal for engaging students. Its physicality is ideal for learners who find classroom learning to be less than inspiring. Students with kinesthetic learning styles or with conditions which have an impact on traditional academic learning, such as dyslexia, will flourish on a visit to a heritage site. It is quite common to see the teachers amazed that the troublemaker or the most disaffected student of their class is taking an interest and engaging in learning when handling artifacts or visiting sites. The fact that we have to

tease out the meanings of heritage through analysis makes it ideal as a tool for learning investigative skills. The prevailing kind of education used by good teachers in schools uses constructivist education theory, which is ideally suited to working with heritage where meanings have to be constructed from mute evidence. Teachers have long known this, and there are national initiatives in England that are designed to get teachers out of the classroom and using built resources in the environment: *Learning Outside the Classroom and Engaging Places*.

The state of cultural heritage education in further education (for ages 16+) and continuing education (part-time adults) is somewhat parlous. Changes to stage funding of these sectors of education have been made in recent years as governments seek to allocate scarce resources to more targeted segments of the population. In particular, they have prioritized funding subsidy for teaching courses leading to vocational qualifications. Subjects like history, archaeology, and history of art or architecture are not deemed vocational, lose subsidy, and have become uneconomic to run. A few colleges and universities still feel that it is important to offer opportunities for a rounded education and are willing to put on courses relating to cultural heritage, but these are now few and far between. Up until the 1990s, part-time courses for adults were the major means by which the adult voluntary sector in history and archaeology gained their up-to-date training in methods, skills, and ideas. Continuing education was the way the professional sector of archaeology supported the large voluntary sector. This is now done massively through project-funded community archaeology.

Future Directions

The future for education about heritage or archaeology is mixed. It will never be a mainstream part of school curricula, where history dominates the study of the past. Good teachers will, however, always value the educational benefits of direct physical engagement with the past. Heritage education will also be marginal to the concerns of field research and heritage conservation. On the other hand, the vitality of the voluntary sector demands a response from professional archaeologists and heritage managers. There will be a demand for training and education of adult volunteers that cannot be ignored. Indeed, this demand represents a great opportunity. Professional researchers can extend the reach of archaeology into areas not represented in mainstream archaeology, for example twentieth-century defense structure or the rural medieval economy, through the work of adequately trained and involved volunteers. The audience for heritage education is there and waiting, it only needs archaeologists to realize it and find the will to go and meet it.

United Nations Convention on the Law of the Sea and Underwater Cultural Heritage

Debra Shefi
Department of Maritime Archaeology, Western Australian Museum, Fremantle, WA, Australia

State of Knowledge and Current Debates

Introduction

Following the Second World War, as a part of the global realignment of power and wealth, states decided to expand their maritime jurisdiction; however, these manoeuvres had ramifications for both the development of national maritime boundaries and international recognition of state control over the seabed's associated resources. The state driven reshaping of maritime boundaries, in conjunction with growing concerns over economic development and national security and an increased accessibility of resources, resulted in State Parties requesting increased international certainty in maritime jurisdictional boundaries. This in part, in 1957, directed the United Nations (UN) General Assembly to adopt Resolution 1105 (XI) (International Conference of Plenipotentiaries to Examine the Law of the Sea), which led to the first Conference on the Law of the Sea in Geneva, Switzerland in 1958.

The aim of the 1958 Conference was to examine the legislative boundaries of the sea, addressing not just the legal boundaries but also the biological, economic, technical, and political aspects across open bodies of water. Discussions culminated in the first United Nations *Convention on the Law of the Sea* (1958) and comprised four independent conventions and an optional protocol: *Convention on the Territorial Sea and the Contiguous Zone* (CTSCZ); *Convention on the High Seas*; *Convention on Fishing and Conservation of the Living Resources of the High Seas*; *Convention on the Continental Shelf;* and *Optional Protocol of Signature concerning the Compulsory Settlement of Disputes*. The 1958 Convention replaced the older "freedom of the seas" perspective, dating to the seventeenth century (Grotius 1633). However, despite the introduction of provisional maritime zones, the defined breadth of each boundary was ambiguously worded. Unfortunately, although discussions leading up to the adoption of the 1958 Convention included "wrecked ships and their cargoes (including bullion) lying on the seabed or covered by the sand or the subsoil" as an area of interest, the concept of cultural heritage was omitted from the text (YILC 1957: 298).

While each of the 1958 UN Conventions identified provisional maritime zones, wording within the individual Conventions relating to jurisdictional boundaries and associated rights to resources remained controversial. Prolonged discussions regarding dissatisfaction with the terms relating to maritime zones followed the Convention, which in 1960, led to a second Conference on the Law of the Sea. However, this conference failed to fulfil the objective of establishing a specific breadth for the territorial sea, as again, Committees could not agree upon any one of the specific proposals put forward (Treves 2008; White 1969). The Conference resulted in the 1960 United Nations *Convention on the Law of the Sea*, but the text did not yield any new agreements, and jurisdictional boundaries remained

ambiguously worded. Once again, underwater cultural heritage remained omitted from the Convention.

As controversial issues regarding jurisdictional boundaries and the continued state of ambiguity concerning the ownership of both living (e.g., molluscs and fish) and non-living (e.g., solid, liquid, or gaseous mineral resources; oil; gravel; or nodules) natural resources remained unresolved, discontent with the Convention continued to grow. By 1974, it was clear that a third Conference on the Law of the Sea was necessary to reconsider a coastal State's jurisdiction over maritime zones and introduce new concepts relating to equitable exploitation of resources within the Area (DOALOS n.d.: 'Economic Exclusive Zone'; UN Convention 1982, Art. 133 [a]; Walker 2012).

This third Conference convened in New York in 1973. Eleven sessions were held between 1973 and 1982, and during this time, 160 sovereign States met to discuss legislative control across the seas, including defining economic, biological, technical, navigational, and political boundaries across open bodies of water and the passage of ships through narrow straits. Many State Parties also felt it was the correct political environment to readdress the safeguarding and management of underwater cultural heritage beyond the contiguous zone (Strati 1995). It was, however, effectively determined that cultural heritage held a low status within the context of the *Law of the Sea,* as it fell short in comparison to the economic potential for the exploitation of natural raw materials and seabed development; this resulted in minimal discussions regarding underwater cultural heritage within the Third Conference (Carducci 2002; Strati 1995).

The final draft of the third United Nations *Convention on the Law of the Sea* (UNCLOS III) was adopted and opened for signature on December 10, 1982, coming into force on November 16, 1994 after the required 60th State Party (Guyana) ratified. The Convention was adopted with the provision that it is to be accepted as a whole – ratification of, or accession to the Convention establishes that the State consents to be bound by all of its provisions. By July 2016, 168 State Parties had agreed to ratification, formal confirmation or accession of the Convention. This is the third *Law of the Sea* Convention adopted by the United Nations, and the first to recognize underwater cultural heritage.

The 1982 Convention

The 1982 Convention comprises 320 articles, set out in 17 parts and 9 annexes, and provides more comprehensive definitions for the 6 identified maritime zones: Internal waters, Territorial Sea, Contiguous Zone, Exclusive Economic Zone, Continental Shelf, and the Area. There are also articles addressing trade, fishing rights, control over natural resources, and the protection of the marine environment within each zone.

Internal waters encompass any waters landward of the baseline of the territorial sea, except in archipelagic states, and include navigable waterways such as lakes, rivers, canals, and bays (Art. 8). The Territorial Sea extends beyond a State's terrestrial territory, which is measured from the low-waterline, and its internal waters, to a belt of sea adjacent to its coast (Art. 2). A State's territory also includes the airspace over the territorial sea and the seabed and subsoil. Every State has the right to establish the breadth of its territorial sea up to a limit not exceeding 12 nautical miles, measured from baselines determined in accordance with the 1982 Convention (Art. 3). The Contiguous Zone is a zone contiguous to the State's territorial sea and may not extend beyond 24 nautical miles from the baselines from which the breadth of the territorial sea is measured (Art. 33). The Exclusive Economic Zone (EEZ) is an area beyond and adjacent to the territorial sea, subject to the rights and jurisdiction of the coastal State and the rights of the freedoms of other States as governed by UNCLOS III (Art. 55). The Continental Shelf includes the continental shelf of a coastal State, the associated seabed and subsoil of the submarine areas that extend beyond its territorial sea throughout the natural prolongation of its land territory to the outer edge of the continental margin, or to a distance of 200 nautical miles from the baseline from which the breadth of the territorial sea is measured where the outer edge of the continental margin

does not extend up to that distance (Art. 76). The Area, or High Seas, includes the seabed and ocean floor and the subsoil thereof, beyond the limits of national jurisdiction within the high seas, and all parts of the sea that are not included in the EEZ, the territorial sea or in the internal waters of a State, or in the archipelagic waters of an archipelagic State (Art. 86).

The 1982 Convention also provides for the establishment of four institutions – the International Seabed Authority, the International Tribunal for the Law of the Sea, the Commission on the Limits of the Continental Shelf, and the Meeting of the States Parties to the Convention. The International Seabed Authority organizes and controls activities pertaining to natural resources in the Area beyond national jurisdiction. The International Tribunal for the Law of the Sea facilitates an international legal framework for settling disputes related to activities on the sea and the uses of its resources. The Commission on the Limits of the Continental Shelf provides recommendations on the establishment of a coastal State's continental shelf outer limit, where it extends beyond 200 nautical miles. The Meeting of the States Parties to the Convention convenes when a Review Conference has been called upon to deal with provisions on natural resource mining in the Area, for amending the Convention, addressing issues of a general nature relating to the Convention, and to elect members of the Commission on the Limits of the Continental Shelf.

Current Debates

After 40 years of discontent regarding the ill-defined maritime zones, the 1982 Convention finally codified agreed upon definitions for jurisdictional maritime boundaries, including a newly introduced Exclusive Economic Zone. The United Nations would like to achieve universal ratification; however, some State Parties remain discontent with Part XI of UNCLOS III, which deals with the mining of natural resources found in the Area, and have identified it as a reason to forgo ratification (de Soto 1983; Malone 1983). In order to rectify the issue, the Secretary-General initiated a series of informal consultations amongst States, which led to the establishment of an *Agreement Related to the Implementation of Part XI of the Convention* in July 1998, but to date, universal ratification has not been achieved. As underwater cultural heritage is not a contentious issue for many States, it was not referenced within the 1998 Agreement.

Of the 320 articles articulated within UNCLOS III, only two address underwater cultural heritage – Article 149 and Article 303. Article 149 *Archaeological and historical objects* specifies that all objects of an archaeological and historical nature found in the Area shall be preserved or disposed of for the benefit of mankind as a whole, with particular regard being paid to the preferential rights of the State or country of origin, or the State of cultural origin, or the State of historical and archaeological origin. No blanket date range or age has been assigned to identify archaeological or historical objects, nor does the text differentiate between archaeological and historical. It is understood that the Article does not apply to modern objects.

Article 303 *Archaeological and historical objects found at sea* similarly remains ambiguous regarding what constitutes archaeological and historical objects. The text establishes that States have a duty to protect these objects and shall cooperate for this purpose (Art. 303 [1]) and that nothing in this article shall affect the rights of identifiable owners, the law of salvage or other rules of Admiralty, or laws and practices with respect to cultural exchanges (Art. 303 [3]). In order to control traffic, the coastal State may, in applying Article 33, presume that the removal of objects from the seabed in the contiguous zone without its approval would result in an infringement within its territory of the laws and regulations referred to in that article (Art. 303 [2]). Article 303 [4] is without prejudice to other international agreements and rules of international law regarding the protection of objects of an archaeological and historical nature; thus enabling future cultural heritage conventions, such as the 2001 United Nations Educational, Scientific, and Cultural Organization's (UNESCO) *Convention on*

the Protection of the Underwater Cultural Heritage, to work in conjunction with UNCLOS III rather than to conflict with it.

While the 1982 Convention addresses underwater cultural heritage, its inclusion in Article 149 and Article 303 do not afford substantive definitions establishing what constitutes archaeological and historical objects. Moreover, the Convention refrains from outlining managerial responsibility or legislative protection for these objects beyond the maximum breadth of the contiguous zone. These ambiguities have an impact on what drives a signatory's domestic policy on underwater cultural heritage legislation. Provisions of international and domestic heritage law only apply to cultural-identifiers or materials identified as needing protection and require legislatively presented definitions of the subject matter in order to afford strong legal protection (Prott and O'Keefe 1984). Without specific reference to what constitutes underwater cultural heritage, or in the case of the 1984 Convention, *archaeological and historical objects*, State Parties can subjectively choose to establish or omit underwater cultural heritage based on the ambiguously presented Articles.

Despite the 1982 Convention recognizing that other international treaties may come into force regarding underwater cultural heritage, such as the 2001 Convention, no other international convention related to navigable bodies of water compares in terms of its international impact. The United Nations comprises of 193 member States; of these, 165 have signed or ratified the 1982 *Convention on the Law of the Sea*. Comparably, UNESCO comprises of 195 member States, but to date, only 57 have accepted or ratified the 2001 *Convention on the Protection of the Underwater Cultural Heritage*. As such, UNCLOS III has a larger global impact regarding underwater cultural heritage management than the 2001 Convention, despite the fact that its inclusion does not afford a robust level of detail regarding appropriate management or identification of archaeological or historical objects. Within the scope of the 1982 Convention, further clarification regarding the ambiguously presented terms is required to effectively manage underwater culture heritage within UNCLOS III and its identified maritime zones.

United Nations Declaration on the Rights of Indigenous Peoples (2007)

Teresa Nichols
Department of Anthropology, Indiana University, Bloomington, IN, USA

Introduction

The UN Declaration on the Rights of Indigenous Peoples (UNDRIP) was formally adopted by General Resolution 61/295 on September 13, 2007, with 144 votes in favor, 4 votes against, and 11 abstentions (Wessendorf 2008). This declaration is the first explicit, international document that lays out the rights particular to Indigenous peoples. However, it is an aspirational document and is not legally binding. This declaration draws upon concurrent movements in the work of the UN Permanent Forum on Indigenous Issues, established in 2000, and efforts during the Second International Decade of the World's Indigenous People (2005–2014) (Schnuttgen et al. 2007). It also builds upon the framework of the earlier Universal Declaration of Human Rights, adopted and proclaimed on December 10, 1948, and the two International Covenants of 1966 (focusing on Economic, Social, and Cultural Rights and then Civil and Political Rights) (Bowen 2000; Silverman and Ruggles 2007). The 2007 UN Declaration and the International Labour Organization's Number 169 "Indigenous and Tribal Peoples Convention," commonly written as ILO 169, form the two most important international legal texts addressing the status of Indigenous peoples and have important repercussions for national and local policies (Jepsen et al. 2017). ILO 169, in comparison to UNDRIP, is a legally binding treaty once a nation has ratified it (Barelli 2012).

Definition

The UN Declaration on the Rights of Indigenous Peoples (UNDRIP) establishes Indigenous peoples as possessing equal rights but also the right to consider themselves different and to be respected as different. It is composed of 46 articles and covers such diverse topics as their right to be free from discrimination and forced assimilation, to practice and revitalize their culture, to establish and control their own institutions, to occupy and access traditional territories, and to self-determination and decision-making. Other issues addressed include labor rights, violence against Indigenous women and children, Indigenous Intellectual property rights, media access and use, relationships to the state, and the commitments of the United Nations to upholding Indigenous rights. The final article, however, includes

the provision that the integrity and the unity of the sovereign nation-state and international human rights obligations take first priority (United Nations Declaration on the Rights of Indigenous Peoples of 2007, see United Nations 2008). A hallmark of UNDRIP is its emphasis on free, prior, and informed consent (FPIC).

Key Issues

After more than 20 years of preparation, the vote for the passage of this document was close, mainly due to the strong political pressure of the CANZUS group (Canada, Australia, New Zealand, and the United States) who dissented (Wessendorf 2008). A major problem for the four dissenting states was related to land claims, addressed most explicitly in Articles 25–29. For instance, although several nations already have systems in place for dealing with Indigenous land claims, most of these do not meet the full measure of intent presented in these articles. Archaeologists have played a role in establishing chronologies of occupation and land use, and these national systems have sometimes used or misused archaeological research in deciding the rights of Indigenous groups to land.

The term "traditional ownership" appears several times, both in the text of the Declaration itself and in the statements of the initially dissenting nations. Without a clear definition in the document itself, what constitutes this "traditional ownership" is left to each nation to decide. How this is conceptualized and turned into policy is critical for Indigenous land rights, and archaeology is often an important line of evidence. Establishing the duration of occupation in an area and the territorial range of these peoples can be important in corroborating a treaty or other forms of recognition. Moreover, there is a tendency to view prehistoric groups as "traditional" and separate from contemporary Indigenous groups, who often do not meet the defining characteristics based on the spread of past material cultures. Demonstrating traditional cultural uses of territory after being removed for long periods of time is difficult especially as cultures easily change, even without the forced assimilation policies common in colonizing societies.

Where the peoples themselves have often been marginalized in the colonial written record, archaeology may allow for more direct links by using material evidence of past societies. Both prehistoric archaeology and contact archaeology have provided important information, even though the use of archaeology in land claims depends greatly on the legal system of the nation and should not outweigh all other lines of evidence or traditional knowledge. New Zealand and Australia have national infrastructures specifically for addressing land claims, while the United States and Canada rely on more general legal processes for dealing with Indigenous rights concerns (Nettheim et al. 2002).

Land and resource-based self-determination as laid out in UNDRIP, as opposed to merely cultural self-determination, further raised concerns over the unity of the nation-state. The Declaration is written in such a way as to support internal self-determination, with territorial integrity (Errico 2007). Article 46 was added at a later stage in the process to ensure this was clearly stated, in an effort to address these criticisms. The original statements in opposition to the Declaration from Canada, Australia, New Zealand, and the United States reflect these concerns. Though Australia in April 2009, New Zealand in April 2010, Canada in November 2010, and the United States in December 2010 formally endorsed the Declaration, it is important to note their original oppositions and reasons.

The Declaration is also significant in that nowhere does it include a definition of the term "Indigenous," preferring that such peoples self-identify. The inability to recognize Indigenous peoples has historically crippled legislation on Indigenous rights. The term arises comfortably as a more neutral one in nations like the United States, Canada, Australia, and New Zealand, where there is a clearly defined separation between earlier occupants and settler colonizers. However, Indigenous peoples throughout Africa, the Americas, Asia, the Pacific, and Europe have all played a part in calling for international legislation such as UNDRIP and are currently engaged

in activism for its implementation in their countries and regions.

There is an ongoing tension in how peoples are recognized by international development organizations or their national governments as either "Indigenous" or an "ethnic minority group," and anthropologists have played a role in shaping this international legal category through "expert testimony, research, and participation in treaty bodies and international legal commissions" (Goodale 2017: 141). Anthropologists are one of many stakeholders in the human rights process, and it is important for anthropologists and archaeologists to reflexively engage with their ethical and professional obligations when working on or with Indigenous peoples. The rise of Indigenous archaeologies especially calls on professionals to rethink the "Us" and "Them" dichotomy that seems inherent in traditional anthropological scholarship and to explicitly recognize the political nature of all heritage studies (Hillerdal et al. 2017).

Future Directions

The Declaration celebrated its 10th anniversary in 2017. As noted above, even though UNDRIP is not legally binding, not all nations initially voted in favor of its passage as an aspirational document. Furthermore, its framing continues to encourage each nation-state to individually consider the Indigenous peoples they recognize within their territories as a special category of ethnic group and as citizens subject to national infrastructures, limiting explicit recognition of Indigenous peoples' self-government and claims to territory (Champagne 2013). Given the delayed endorsement of UNDRIP by the CANZUS group, there is concern that this "selective endorsement" already signaled that some nations were not willing to substantially change their policies and practices to implement the Declaration (Lightfoot 2012). While some countries, most notably Bolivia, wrote aspects of the Declaration into their national law, UNDRIP still remains as more of a benchmark than an international baseline of policy (Jepsen et al. 2017).

Article 32, Section 2 of UNDRIP established that:

> States shall consult and cooperate in good faith with the indigenous peoples concerned through their own representative institutions in order to obtain their free, prior, and informed consent prior to the approval of any project affecting their lands or territories and other resources, particularly in connection with the development, utilization or exploitation of mineral, water or other resources.

FPIC is now widely recognized by international and national organizations and their policies, and the Inter-American Court of Human Rights has upheld the approach that "when a development project is likely to have a serious (negative) impact on their cultures and lives of indigenous peoples, States must obtain their consent before implementing it" (Barelli 2012: 32). However, exploration and exploitation of natural resources as well as renewable energy projects and tourism are continuing to have significant, negative impacts on Indigenous peoples as both states and industries do not uphold the principle of FPIC and vary in their processes of consultation (Jepsen et al. 2017). It can be argued that there is no incentive within UNDRIP itself to encourage nation-states to recognize the rights of Indigenous peoples within their own forms of social and cultural organizations and collective orientations to land (Champagne 2013).

Engaging with Indigenous peoples prior to the start of development or archaeological projects and respecting their right to consent, not merely to be consulted, is an ongoing issue that has yet to become standard practice around the world. The political constructions of Indigenous identities and the reclamations of heritage continue to move the work of archaeologists beyond academic scholarship into the realm of present-day events and economic, cultural, and political repercussions. As Niezen reflects, "law has a uniquely powerful capacity to create entities out of abstractions," and archaeologists should be cognizant of human rights frameworks in the places they live and work (Niezen 2017: 30).

United States: Cultural Heritage Management

Ricardo J. Elia
Department of Archaeology, Boston University, Boston, MA, USA

Introduction

The protection and management of cultural heritage in the United States comprises a complex mosaic of government, local, and indigenous stakeholders interacting within a federal political system with a strong tradition of private and entrepreneurial involvement (McManamon 2000; Murtaugh 2006). In the United States, the protection afforded to cultural resources depends on where the resources are located and who owns them. One-third of the US landmass, concentrated disproportionately in Alaska and the westernmost states, is federal property, and there are heritage sites effectively owned and managed by the national authorities. The remaining two-thirds is owned by state, municipal, and private entities; the ability to manage heritage sites in this area varies considerably. Properties on state lands may enjoy the full protection of preservation laws, while cultural heritage protection on privately owned lands is generally negligible given the strong influence of private property rights in the American legal tradition. In addition to its 50 states and several territories, the United States is home to 565 federally recognized Indian tribes as well as numerous other tribes recognized at the state level and a host of ethnic and minority populations, all of which have a stake in cultural heritage preservation.

Key Issues/Current Debates/Future Directions/Examples

The preservation movement in the United States began in the nineteenth century when groups of private individuals initiated efforts to preserve buildings and sites associated with important personages in the nation's early history (e.g., George Washington's Mount Vernon Estate and Andrew Jackson's Hermitage). Patriotism and moral instruction were the chief motivating factors driving preservation until the twentieth century, when aesthetic interests relating to the preservation of buildings, furniture, and other cultural objects assumed prominence (Murtaugh 2006: 11–23). Little attention as yet was paid to archaeological sites, but historic houses, house museums, historic villages (e.g., Colonial Williamsburg in Virginia and Greenfield Village in Dearborn, Michigan), and historic battlefields (often originally acquired by the military for instructional purposes) were common by the middle of the twentieth century. In 1949, the congressionally chartered National Trust for Historic Preservation was created to promote preservation of nationally significant "sites, buildings, objects, and antiquities" and to facilitate public participation in the same (Murtaugh 2006: 172). The National Trust is a private, nonprofit organization that owns a small group of historic properties and continues to serve as a focal point for education, advocacy, and information about preservation in the United States.

The federal government's role in cultural heritage preservation began haltingly in the late nineteenth/early twentieth century but has grown steadily in importance and influence since that time. Today federal involvement dominates the preservation field in terms of legislation, policy, and funding. In 1892, the ruin of a deteriorating prehistoric pueblo at Casa Grande, New Mexico, was rescued by a presidential executive order following a lobbying campaign led by concerned citizens (McGimsey and Davis 1984: 116–117). Later, a 6-year advocacy effort by scientific and archaeological organizations to deter rampant commercial exploitation and vandalism of other prehistoric sites in the American Southwest resulted in passage of the first federal preservation legislation, the Antiquities Act of 1906 (Harmon et al. 2006). The Antiquities Act outlawed unauthorized excavation, damage, or removals from archaeological and historical sites, monuments, and objects on federal lands and authorized the president to preserve sites, structures, and objects of archaeological and scientific interest by declaring them national monuments. Cultural and natural sites were steadily reserved as national monuments and parks in the years following passage of the Antiquities Act. In 1916, this activity received additional stimulus by the creation of the National Park Service, which assumed responsibility for management of the national parks. Today the National Park Service manages almost 400 national parks in 50 states, comprising 84,000,000 acres of land containing more than 68,000 archaeological sites and 27,000 historic structures (National Park Service n.d.).

Preservation of cultural heritage became the official policy of the United States in the 1935 Historic Sites Act, which declared that "it is a national policy to preserve for public use historic sites, buildings and objects of national significance for the inspiration and benefit of the people of the United States" (quoted in Murtaugh 2006: 172). This often-overlooked law is significant for the way for its encouragement of public-private partnerships dedicated to preserving cultural heritage; in that sense, it foreshadows some of the provisions of the later National Historic Preservation Act of 1966, which adopt a similar approach. The Historic Sites Act encouraged the collection of data regarding heritage sites, including "a survey of historic and archaeologic sites, buildings, and objects," regardless of whether the sites were publicly or privately owned. The Secretary of the Interior was also empowered to make cooperative agreements – again, with both public and private entities – to protect cultural heritage of significance to the nation and to acquire, restore, and operate the same. The Historic Sites Act became the basis for the creation of the National Historic Landmarks program (McGimsey and Davis 1984: 118; Murtaugh 2006: 43–44).

The federal government's ability to manage archaeological heritage was greatly strengthened

by the passage of the Archaeological Resources Protection Act (ARPA) in 1979. This law makes the excavation of archaeological sites on federal and Indian lands without a permit illegal; establishes criminal penalties for looting, vandalism, and destruction of sites; and prohibits the sale, purchase, exchange, transport, export, and receipt of archaeological resources obtained illegally. The 1988 amendments to ARPA require federal agencies to survey their lands for archaeological resources and to promote public awareness of the importance of heritage preservation. During the 1990s, a series of high-profile prosecutions and legal cases confirmed ARPA's status as an effective anti-looting tool, applicable in certain situations even to activities on private land (Hutt et al. 1999: 188–232).

Management of cultural heritage on both public and private lands received a dramatic boost with the passage of the National Historic Preservation Act (NHPA) of 1966. Later amendments, executive orders, and regulations, as well as complementary environmental legislation, have turned the NHPA into an effective tool for protecting and managing historical sites, landscapes, and archaeological resources at not only the federal level but in the state, local, and private spheres as well. The NHPA established an inventory of significant cultural properties, called the National Register of Historic Places (King 2008: 87–107), and encouraged states to create State Historic Preservation Offices (SHPO) in order to develop plans for the identification and management of cultural resources, administer grant programs for local preservation projects, and review projects for compliance with federal law. The NHPA also created a federal agency called the Advisory Council on Historic Preservation to provide comment and advice on proposed federal actions affecting cultural heritage. The 1992 amendments to the NHPA allow federally recognized Indian tribes to develop Tribal Historic Preservation Offices to carry out the same preservation functions as the SHPO on the state level and created a research unit of the National Park Service called the National Center for Preservation Training and Technology.

One of the most significant features of the NHPA is its "Section 106" provision that requires federal agencies to "take into account" the effect of their actions on significant cultural sites (King 2008: 109–206). This requirement applies not only to direct actions by federal agencies (e.g., construction of a new road in a national forest) but also to federally assisted actions, many of which take place on, or affect, private property. For example, because proposed construction of an interstate natural gas pipeline requires a permit from the Federal Energy Regulatory Commission and is therefore a "federally assisted action," Section 106 of the NHPA would trigger surveys for archaeological sites and historic properties of the areas affected by the construction even if the "impact areas" were all located on private property. The approach adopted in Section 106 is noteworthy and perfectly suited to the US situation. First, it requires every federal agency, not a single authority (the United States, unlike many nations, has no ministry of culture), to assume responsibility for preservation. This diffusion of legal responsibilities for preservation makes sense because multiple federal agencies have direct control over cultural heritage on lands they manage. Overtime preservation planning has become an established, integrated component of US federal agency activities, and most US land-managing or land-developing agencies now have professional staffs including archaeologists, architectural historians, and preservation planners. Second, Section 106 requires preservation on affected private lands without challenging the traditional primacy of private property rights; it does this by imposing regulatory requirements for preservation to ensure that significant cultural heritage is not destroyed through the activities of federally funded or federally assisted projects carried out on private lands. Thus, the NHPA affords welcome, albeit limited, opportunities to identify and protect cultural heritage located on private property, where cultural heritage found on or beneath the soil generally belongs to the private landowner and is otherwise subject to little, if any, regulation.

The NHPA dramatically transformed the US system of cultural heritage management and is largely, though not solely, responsible for shaping

the modern discipline of cultural resource management in the country. It enhanced the responsibilities of the National Park Service beyond its park-management functions within the U.-S. Department of Interior to the point that the agency has become the premier preservation agency for the country. Home to the National Register of Historic Places, National Historic Landmark Program, Heritage Documentation Programs, and National Center of Preservation Technology and Training, the Park Service provides vital advice and consultation for the numerous federal agencies that have responsibilities for preservation and management under the NHPA, ARPA, and other legislation. The NHPA also is responsible for the creation of the Advisory Council on Historic Preservation, a federal agency, and for state and tribal preservation offices (SHPO, THPO). Today every state and territory has a SHPO; they serve as highly visible centers for the coordination of preservation efforts in their areas. Many states have enacted legislation to protect and manage cultural heritage on state lands or affected by state-funded or state-assisted projects, much as NHPA does on the federal level. There are also currently 118 THPOs performing heritage-related and compliance functions for Native American tribes in 28 states (National Association of Tribal Historic Preservation Officers n.d.).

By requiring review of projects for their effects on cultural sites, the NHPA also stimulated the emergence of a veritable cultural resource management industry that employs thousands of private consultants, entrepreneurs, and government specialists who are either involved in conducting archaeological and historic preservation studies or reviewing them in accordance with government laws and regulations (McManamon 2000). The growth of non-academic professional archaeology in particular was affected by this development; the new field of "contract archaeology" not only provided a welcome source of professional employment but also in turn influenced the more traditional, academic field of archaeology as new engagement with public and private stakeholders engendered a rethinking of professional ethics and practice, which has come to be known as "public archaeology."

For most of the twentieth century, federal legislation and policy equated cultural heritage protection with the national interest, that is, a unitary, shared public interest that all Americans might embrace. Two important laws late in the century reflect a more fragmented view of cultural heritage rights. First, the 1987 Abandoned Shipwreck Act removed abandoned shipwrecks in the 3-mile US territorial waters from the jurisdiction of federal admiralty courts, where they had been regularly seized by treasure hunters intent on mining them for commercial profit and assigned their title to the states. Unfortunately many of the states still have regressive laws that encourage commercial salvage of historic shipwrecks while imposing some level of archaeological oversight. The Abandoned Shipwreck Act also recognizes treasure hunters as valid stakeholders, in contrast to the situation on federal lands, where looters of archaeological sites are subject to criminal prosecution (Elia 2000: 46–47).

Second, the Native American Graves Protection and Repatriation Act (NAGPRA) of 1990 gives two groups – Native Americans and Native Hawaiians – special rights to recover and own affiliated cultural heritage (Hutt et al. 1999: 232–248; King 2008: 260–270). This law establishes a mechanism for the repatriation of certain human remains, funerary objects, sacred objects, and objects of cultural patrimony both from federal lands and from museums and other curatorial institutions. In addition to helping to redress historical inequities in the often-troubled relationship between these indigenous groups and mainstream Euro-American culture, NAGPRA also requires consultation among archaeologists, federal agencies, museums, and the native groups. This obligation to consult has proven to be one of the most salutary effects of NAGPRA and has helped to promote the active involvement of indigenous populations in the US preservation system as well as a greater understanding among the various stakeholders.

The federal government's role in cultural heritage management has been decisive domestically since the 1960s, as has the constructive

involvement of the states through their SHPOs and, to a lesser extent, the municipalities through encouragement of preservation through zoning and other local regulations. Even so, the importance of the private sector should not be overlooked. More historic buildings and house museums are certainly owned by private individuals and groups than by government, and the same is true for museums and other cultural attractions. Public ownership of archaeological sites is the only exception to this pattern, in the sense of recorded sites that have been brought under effective control for management purposes, although even in the case of archaeology some private organizations (e.g., the Archaeological Conservancy) are acquiring sites for the purpose of preservation.

At the international level, the United States has a mixed record of participation in conventions relating to cultural heritage. It signed the 1954 Hague *Convention for the Protection of Cultural Property in the Event of Armed Conflict* in 1954 but only ratified the treaty in 2009 after a difficult and controversial experience following the invasion of Iraq in 2003 that witnessed the looting of the Iraq Museum and the pillaging of numerous archaeological sites. The United States ratified the 1970 UNESCO cultural property convention in 1983 but has not ratified the 1995 UNIDROIT *Convention on Stolen or Illegally Exported Cultural Objects* and shows no signs of moving in that direction. It did ratify the 1972 World Heritage Convention and currently has eight cultural properties, twelve natural properties, and one mixed property listed on the convention, with several nominations pending. Finally, the United States has not taken steps to ratify either the 2001 UNESCO *Convention on the Protection of the Underwater Cultural Heritage* or the 2003 UNESCO *Convention for the Safeguarding of the Intangible Heritage*.

In sum, the US system of cultural heritage management is a thriving, dynamic, and imperfect enterprise involving specialists, entrepreneurs, government and private actors, and a host of interested parties working to protect and preserve historic buildings, landscapes, districts, archaeological sites, national landmarks, national heritage areas, and cultural objects. Although serious problems continue to affect the field, including the challenge of protecting cultural heritage on private property, chronic underfunding for heritage projects, and periodic legal challenges to preservation legislation, cultural heritage management is a well-established fact of American life and public awareness of the value of preservation is at an all-time high.

United States: Cultural Heritage Management Education

Susan J. Bender
Department of Anthropology, Skidmore College, Saratoga Springs, NY, USA

Introduction

Since the Society for American Archaeology issued its turn-of-the-century call for a renewed vision for archaeology education (Bender and Smith 2000), a profound change has taken root in this endeavor. Contributors to the 2000 SAA volume noted that the conceptual structure of archaeology's curricula had changed little since the mid-twentieth century, despite significant advances in method, theory, data accumulation, and the contexts in which archaeological research was conducted. Major advances in scientific data acquisition techniques, analytical methods, and theoretical modeling had kept academic archaeologists' vision of the discipline centered on its historiographic research aspects, yet at the same time the introduction of historic preservation law in the USA introduced a specifically public context for the discipline's practice. In 2000, the call was for those who teach archaeology to acknowledge its public dimensions and begin to train students to understand and function effectively in the latter contexts as well as in traditional research dimensions. Those scholars who adjured their colleagues to take heed of the need for such revision emphasized the notion that archaeological practice extended beyond pure research, but they still conceptualized the archaeological record traditionally: as a finite, material resource to be understood through the methods of science.

In response to those early efforts, which were heavily influenced by the contemporary articulation of the Society for American Archaeology's standards for archaeological ethics (Lynott and Wylie 2000), a new paradigm for archaeological education began to emerge through such initiatives as the MATRIX project (http://www.indiana.edu/~arch/saa/matrix/homepage.html). The conversations engendered by this work encouraged archaeologists to explore the many public dimensions of archaeological practice and their consequences for archaeology curricula. Soon traditional concepts such as "The Past" and its material manifestations, "Archaeological Resources," became subsumed in the more broadly conceived and socially contextualized concept of "Heritage," broadly defined as "the full range of inherited traditions, monuments, objects, and living environments, and [extending to] the range of contemporary activities, meanings, and behaviours that are drawn from them" (Chilton and Mason 2010). As this conversation unfolded, notions of the archaeological practices of historic preservation and cultural resource management became more broadly situated in the attendant domains of heritage studies or heritage management.

Definition

In all their manifestations, heritage studies programs are highly interdisciplinary and require that students develop an understanding of archaeology practice as it is inflected by the theoretical and methodological perspectives of such disciplines as history, sociology, sociocultural anthropology, architecture, environmental biology, communications, historic preservation, literature, and urban and rural planning. Under this rubric, students of archaeology develop a concept of a past that is recorded not only through tangible heritage, commonly thought of as archaeological resources, but also through the intangible, defined as "The

practices, representations, expressions, knowledge, skills. . .that communities, groups, and in some cases, individuals recognize as part of their cultural heritage" (Ahmad 2006: 298). Managing a heritage thus defined not only requires knowledge and skills developed through scientific approaches to the past but also those rooted in the humanities.

Heritage studies and management programs are also focused on archaeological practice, as were their predecessors, cultural resource management programs, and, like their predecessors, heritage programs regularly emphasize the applied dimensions of their courses of study – specifically, teaching students to become effective professionals in heritage planning and management (cf. University of Maryland, Graduate Studies; University of Massachusetts, Center for Heritage Studies; Texas Tech University, Heritage Management Program). Beyond this shared concern with professional practice, Heritage Studies and Management programs differ markedly from their forebears in their notions of what is entailed in such practice. Programs moving to a heritage focus are generally heavily centered on developing expertise in arenas originally mapped out by British and European scholars, including such elements as developing an understanding of the effects of collective memory on historical narratives and learning how to engage processes that can articulate the many meanings and values associated with the material fabric of the past (e.g., Lowenthal 1985; Stone and Molyneaux 1994; Stone and Planel 1999; and Zerubavel 1996). Students in programs with a heritage focus are encouraged to think critically about how best to administer and conserve heritage and landscape in lieu of resources and sites.

Formal degrees awarded through Heritage Studies and Management programs are usually confined to the master's, although a few also offer a doctoral program. In the latter instance, the emphasis on practice is coupled with an emphasis on original research (cf. University of Maryland, Graduate Studies; Indiana University, Center for Archaeology in the Public Interest).

Key Issues

Heritage Studies and Management programs are a relatively new phenomenon in United States academic institutions. The first programs to use this nomenclature emerged at the turn of the twenty-first century, and a number are currently under development or recently announced. This nascent status brings with it several challenges as well opportunities.

The challenges to these programs center on the definition of heritage studies academic structure and, in particular, the role of archaeology within such a highly interdisciplinary undertaking. The student who is interested in pursuing a heritage studies program has to search under many different program umbrellas to find the desired course of study. Some programs reside in independent centers (e.g., University of Massachusetts, Center for Heritage and Society; Montclair State University, Center for Heritage and Archaeological Studies; Texas Tech University, Center for Advanced Study of Museum Science and Heritage Management), although only the latter offers a degree program. Others are imbedded in historic preservation programs (e.g., University of Pennsylvania; University of Florida; Georgia State University), while still others are offered as specialized tracks – frequently applied – within anthropology programs (e.g., Indiana University; University of Maryland; University of Minnesota). In keeping with this variety of disciplinary homes, there is only minimal agreement among proscribed curricula, beyond the requirement of practical training in the form of an internship, practicum, or fieldwork. Method requirements range widely from standard archaeological and/or archival methods through qualitative and quantitative methods to innovative video and digital applications. Only a few core courses in heritage studies or heritage management can be found listed within these programs, and at least some seem to be only marginally altered from earlier historic preservation or cultural resource management programs. It is to be hoped that academic institutions in the United States might

move toward a greater uniformity in the institutional placement of heritage studies. Such alignment might go far toward resolving the issues surrounding heritage studies curricula.

Since the theoretical underpinnings of heritage studies rest as much in history and sociology as in anthropology, the relationship between heritage studies and traditional archaeological curricula is particularly unclear. The most interdisciplinary of the Heritage Studies and Management programs decenter the study of archaeology and include it as yet another, sometimes optional, component in the course of study. Such programs emphasize the social dialogue around the interpretation, preservation, and administration of heritage and seek to make archaeological concerns a component in a set of overlapping and equally legitimate perspectives on the academic and social dimensions of heritage. In contrast, programs that imbed heritage management in anthropology curricula tend to proscribe programs of study that emphasize the links between archaeology and sociocultural anthropology through required courses in field and analytical methods, theory, and in some cases ethics. Where the Heritage Management Program is offered as a degree in applied anthropology, the course of study often mimics earlier cultural resource management programs with its emphasis on gaining professional archaeological skill sets – including working knowledge of the preservation law that surrounds archaeological practice. Indeed, as heritage management programs continue to replace cultural resource programs in the academy, it will be critical to resolve the issue of how to integrate a robust study of core heritage theory and practice with traditional training in archaeological practice. Here a key question is "how much can traditional archaeological training be attenuated to allow for training in allied disciplines that claim the past as their subject of inquiry, as well?" Clarity around the differences between cultural resource and heritage management study is essential, along with a definition of the knowledge and skills that a heritage manager with archaeological expertise should possess. The resolution of these issues might then inform the development of Heritage Management Programs, many of which have been inaugurated without benefit of such clarity.

The opportunities presented by the new Heritage Programs are, at the same time, striking. As students in these programs develop the knowledge and skills involved with practicing archaeology in a broad sociocultural and academic context, professional archaeologists will become engaged in a multivocal conversation about the meanings of the past and the most effective ways of preserving and interpreting it – especially in the service of larger social programs that may seek to develop national or local identities or economic opportunity through heritage tourism. Such a dialogue will inevitably require that archaeologists articulate the meaning and importance of the discipline to a broad and diverse audience. Successful engagement in this exchange should strengthen disciplinary practice as well as recruitment of a diverse group of young professionals. Moreover, since the conversation about heritage is at its foundation international (Ahmad 2006), US archaeologists will need to reflect on their practice in a broader arena, one that includes indigenous voices as well as professional perspectives from around the world and that demands reference to the ethical parameters of studying the past. The professional self reflection required by such developments can only lead to an engaged practice with wider credibility and viability in the United States.

Urals: Paleolithic

Jiri Chlachula
Laboratory for Paleoecology, T. Bata University in Zlin, Zlin, Czech Republic
Institute of Geoecology and Geoinformation, Adam Mickiewicz University, Poznan, Poland

Introduction

The Ural Mountains, forming a natural physiographic boundary between Europe and Asia, was a key loci of the Paleolithic and Mesolithic occupation. The mountain regions with the adjoining areas of the East European Plains and the West Siberian Lowland have principal significance for documenting the processes and natural contexts of the Pleistocene human expansion from the SE parts of the European continent into West Siberia and the northern Russian Arctic. Past climate change and the regional topographic modeling by orogenesis and the Pleistocene glaciations, reflected by the marked environmental transformations of past landscapes and biota, attest to the complexity of the Urals' Quaternary development ultimately determining timing and the extent of the earliest hominid inhabitation of this territory. The initial peopling of the western (Fore-Ural) area is linked to the Paleolithic dispersal into the marginal East European Plain probably during the climatically favorable Middle Pleistocene interglacials. The southern and central river valleys, transecting the mountain ranges, were the main geographic corridors of the later (Middle and Upper Paleolithic) migrations into the eastern (Trans-Ural) regions of

West Siberia. A progressing evolution during the Late Pleistocene reflected a behavioral adjustment resulting in formation of specific regional cultural complexes in the mountain areas and the foothills based on exploitation of reindeer and the "mammoth fauna" in the northern periglacial tundra-steppe, respectively. Geoarchaeology records from diverse settings provide insights into the timing and ecology conditions of the Pleistocene colonization of the north-central Eurasia and evidence on the trajectories of the Quaternary environmental development in the broader Urals.

Definition

The Urals and the adjoining regions of the East European Plain (*Priuralye* – the Fore-Urals) and the West Siberian Lowland (*Zauralye* – the Trans-Urals) (Fig. 1) are of a major relevance for the Paleolithic studies in respect to the particular geographical location along the border zone between Europe and North Asia. Except for documenting the cultural development and adaptation strategies in the context of Pleistocene climate and environmental change, the broader territory of the Urals has a principal bearing for mapping timing and natural conditions of the initial human migrations into the subpolar and polar regions of Eurasia. The paleoenvironmental proxy data related to early peopling of this territory originate from the river-eroded subaerial deposits (loess-paleosol sections) in the Kama Basin, the karstic cave sites in the Chusovaya River valley transecting SE-NW the Central Urals, and from genetically diverse (aeolian, colluvial, and alluvial) Quaternary formations along the eastern slopes of the Ural mountain range and the valleys draining the western margin of the West Siberian Plain. The broad variety of the cultural data provides witness to several stages of early inhabitation of the Ural region ecosystems, likely encompassing a time span over 0.5 Ma. The earliest (Middle Pleistocene) finds are represented by the typical "pebble tool"

Urals: Paleolithic, Fig. 1 A geographic map of the Urals with the main continental drainages of the Fore-Urals (the Kama and the Pechora Basins) and the Trans-Urals (the Ob River Basin). The principal Paleolithic research relates to the southern, central, and the NW region of the Ural territory

industries, followed by the Middle Paleolithic traditions including the Levallois prepared-core stone-flaking technology, and the Upper/Final Paleolithic blade complexes eventually replaced by a variety of the Mesolithic cultural facies illustrating the major regional ecological shifts during the Pleistocene/Holocene transition (12,000–10,000 years ago) of the Ural region ecosystems. The Ural is also World-known for the Paleolithic cave art (Kotov 2009).

At present, there are several hundred of Pleistocene sites mapped over the investigated Ural territory. The long-term interdisciplinary research focus is on geology and paleoecology contexts of single localities, taphonomy, and chronostratigraphy. Apart of the spatially confined cultural locations, especially the large-scale fluvial erosions cutting the loess plateau of the Fore-Urals (the Upper Kama Basin) and the floodplain deposits of the Trans-Ural river valleys provide a major source of paleontological and paleobotanic records in the framework of the Pleistocene regional climate change reconstructions. Evolutionary pathways and processes in natural environments, the specific behavioral Paleolithic adaptation patterns and material-technological conditions, as well as documentation of sequenced climatic events stored in the geological records are the principal objectives of the current multidisciplinary Quaternary geology, paleoecology, and geoarchaeology studies.

Historical Background

Natural transformations in the Urals and the adjacent foothill/plain areas are evidenced by the stratified geological, biotic (floral and faunal), as well as rich early cultural records. Interactions of the Quaternary climatic variations with the regional topographic modeling by the northern Arctic glaciations and the interglacial transgressions, the Pleistocene neotectonics triggering landscape erosion, and stages of surface stability with pedogenic weathering indicate the complex environmental development of the Ural area. The continental orogenic activity in conjunction with the glacial dynamics and fluvial erosion shaped the regional relief. During the cold Pleistocene periods, the vast extra-glacial areas of the adjoining West Siberian Lowland south of the Arctic ice sheet were periodically transformed into large periglacial zones – major sedimentation catchment areas of aeolian as well as glaciofluvial and lacustrine deposits transported from the continental NE European and NW Siberian Arctic ice-margin ablation surfaces. The cyclic nature of the glacial and interglacial periods led to a restructuring of the past landscapes and generation of specific ecosystems adjusted to particular topographic settings and responding to ongoing climatic variations, contributing to formation of biotically productive river valleys particularly along the Ural foothills.

The paleoenvironmental transformations promoted the western and northern geographic expansion of early humans into the subpolar regions of central Eurasia as well as the progressive cultural adaptation to extreme natural conditions. The mapped occupation sites in the Polar Urals and North Siberia (Mochanov and Fedoseeva 2002; Svendsen and Pavlov 2003; Pitulko et al. 2004) provide proof that people reached the (sub-) Arctic including the northernmost coastal areas already well before the Last Glacial (>24,000 years ago), likely >40,000 years ago (Svendsen et al. 2010; Pitulko et al. 2016, 2017). All these discoveries lead to revision of the traditional perceptions on a late peopling of northern Asia as well as the obsolete "postglacial" chronology models of the initial human migrations across the exposed landbridge of the Pleistocene Beringia into the North American continent (Chlachula 1996, 2003). Geoarchaeology studies, particularly in the poorly explored geographic regions – the Polar Urals and the NW West Siberia – are of utmost importance for reconstruction of Quaternary climate change as well as the early human prehistory in north Eurasia. The present status of the geo- and environmental archaeology research in some of the marginally mapped geographical areas of the Northern Urals reflects a limited accessibility of these territories, visibility, and/or the preservation potential of the Paleolithic records comparing to the better-investigated central and especially the Southern Ural regions.

Key Issues/Current Debates

The Urals with the bordering plains of Eastern Europe and West Siberia are of key importance for multidisciplinary Quaternary investigations focusing on the initial peopling of north-central Eurasia because of the strategic geographical position of this mountain chain, forming the natural borderline between Europe and Asia. Apart from mapping the Pleistocene and Holocene climate evolution and the associated landscape ecology transformations, the territory of the Urals has a major relevance for reconstruction of the time intervals of dispersal of the Pleistocene hominids/early humans into the high latitudes of Eurasia and documentation of cultural adaptation strategies to past climate variations. The current scientific debates primarily focus on the regional chronologies' improvement and interpretations of Paleolithic environmental adaptation strategies.

Natural Context, Paleogeography, and Climate History

The Ural Mountains extend as a major geographic landmark between Europe and Asia for over 2,000 km from the Arctic coast to the arid steppes of western Kazakhstan (Fig. 1). The five physiogeographic zones, connecting the Southern Urals with the Northern, Subpolar, and Polar Urals, are characterized by a marked latitudinal vegetation zonation with polar tundra-forest, taiga, and open steppe being the dominant biotopes. Most of the regional relief (700–1,895 m asl.) is transected by mountain valleys with the E-W oriented fluvial drainage following the continental topographic gradient (Fig. 2). The adjoining geographical area in the West (Fore-Urals) includes the loess plateaus of the Upper Kama and Pechora River Basins. The eastern (Trans-Urals) area is delimited by the Tobol and Ob River Basins with the tributary valleys (Severnaya Sosva, Sosva, Tura, Tagil, Neiva, Pyshma) cutting the foothills. Small hills (300–400 m asl.) between shallow river valleys, lakes, and bogs extend further east into the West Siberian Lowland. The present climate over the Ural Mountains is controlled by the NW Atlantic atmospheric circulation. The soil cover is characterized by well-developed parkland-steppe chernozems, mixed/coniferous taiga forest brunisols/gleysols, and forest-tundra regosols. The topographically and biotically diverse territory attests to a complex paleogeography and paleoecology history reflecting large-scale regional landscape restructurings affected by the Cenozoic orogenesis, periodic sea transgressions and regressions, and the Arctic and mountain glaciations (Velichko 1993; Astakhov 1997, 2001; Mangerud et al. 2002). The Fore- and Trans-Ural plains constitute a continuation of the Eurasian loess

Urals: Paleolithic, Fig. 2 The Urals, modeled by tectonics and Pleistocene glaciations, create a natural boundary between Europe and North Asia. View of the eastern slopes of the subpolar Ural Mountains / the northern Transurals descending into the West Siberian Lowland (the lower Ob Riber basin) with alpine tundra vegetation. The Khanti-Mansiysk Autonomous Region.

belt connecting the European and Siberian loess regions. The regional Quaternary stratigraphy is based on geological, paleontological, biostratigraphic, and paleomagnetic records of the continental basin transgressions and regressions and stages of loess deposition.

The pre-Quaternary (Miocene-Pliocene) history of the Urals is connected with the formation of the initial hydrological systems in the Fore-Urals (the Pechora, the Volga-Kama, and the Caspian Basins) as well as the Trans-Urals (the Irtysh-Ob Basin) triggered by the contact orogenesis of the Eurasian Plate in conjunction with long-term climate variations. During warm climatic stages, the continental basins were filled by seashore marine, fluvial, and lake deposits superimposed by periglacial alluvial formations (Yakhimovich et al. 1987; Stefanovskiy 2006). The Early Pleistocene interglacial biotic records document a forest-steppe habitat with arboreal taxa absent in the area today (*Fagus*, *Acer*, *Fraxinus*, *Ulmus*, *Tilia*, *Castanea*) and brackish settings inhabited by large faunal species such as *Archidiskodon meridionalis*, *Hipparion* sp., and *Coelodonta* sp. Climatic cooling at the end of the Early Pleistocene (740 ka BP/thousands of years ago) is manifested by glacial deposits distributed in the Pechora and the Upper Kama Basins, with the continental coastline expansion due to the regressions of the Caspian Sea and the Arctic Ocean.

The reactivated tectonics at the beginning of the Middle Pleistocene in the Urals-Caucasus area accelerated a restructuring of the former regional drainage systems. Increased aridity put up to an intensified weathering in the mountain areas. A reduced riverine activity in the adjacent West Siberian Lowland contributed to genesis of closed-lake and boggy basins. Floral and faunal communities indicate dry steppe environments replacing the former Mediterranean-type woodlands with *Pterocarya fraxinifolia*, *Rhododendron* sp., *Taxus baccata*, and *Castanea sativa* (Stefanovskiy 2006). The new hydrological network of the Tobol (MIS 9) Interglacial (390–270 ka BP) corresponds to the 60 m terrace with the Tiraspol Fauna Complex including herbivorous megafauna (*Paleoloxodont* sp., *Mammuthus primigenius* Blum., *Bison priscus gigas*, *Alces alces*, *Megaloceros giganteus*, *Cervus elaphus*, *Equus hemionus*, *Equus caballus*, *Camelus* sp., and *Ovis ammon* sp.) indicative of warm semiarid parklands. The following Samarovo (MIS 8) Glacial (270–244 ka BP) correlates with the maximum expansion of the Arctic ice blocking the northern Ob/Irtysh River drainage of the West Siberian glacial waters diverted south into the Aral-Caspian Basin. Temperate parklands characterized the following Shirta (MIS 7) Interglacial (244–170 ka BP). A geographic recession of ice masses is assumed for the Tazov (MIS 6) Glacial (170–130 ka BP) with mountain glaciers confined to the Northern and Polar Urals. The late Middle Pleistocene in the south-central basins is associated with fossil fauna of the Khozarian Complex (*Mammuthus primigenius*, *Coelodonta antiquitatis*, *Bison priscus longicornis*, *Megaloceros giganteus*, and *Equus caballus chosaricus*) found in alluvial formations indicative of moderately cold environments. A final Middle Pleistocene neotectonic stage accentuated the regional geomorphological relief restructuring due to continuing uplifts of the Central and Southern Ural mountain ranges.

A reduced regional topographic differentiation during the early Late Pleistocene is associated with planation processes in the Trans-Ural area and the Last Interglacial (MIS 5e, 130–120 ka BP) transgression. The Ural foothills were covered by a mixed spruce and pine-dominated taiga; open parklands occupied the lowlands hosting the "Mammoth Fauna Complex" (Bolikhovskaya and Molodkov 2006). The regional stratigraphy and glacial geomorphology reflect reducing geographical limits of the continental ice masses during the early/Zyriansk (MIS 4) and the late/Sartan (MIS 2) Last Glacial stages. Large ice-dammed lake between the northern Arctic ice sheet and the southern continental water divides inundated most of the West Siberian Lowland during the early Last Glacial (c. 80–60 ka BP). Moraines in the Pechora Basin on the NE European Plains point to the expanding Arctic glaciations from the Kara – Barents Sea ice lobes presumably reaching their maximum Late Pleistocene extent similarly as in West Siberia (Astakhov 1997,

2001). Dynamic climatic fluctuations during the second half of the glacial stage caused a gradual recession of the continental ice limits in the Northern Urals and activation of intensive periglacial gravity-slope processes contributing to massive accumulations of polygenic colluvia in the Trans-Ural foothills. Deposition of up to 20 m of loess sediments on the Fore-Ural plateaus, overlying periglacial alluvia of the Upper Kama, reflects the prevailing dry and cold climatic conditions within the Late Pleistocene periglacial tundra-steppe.

The subsequent mid-Last Glacial (MIS 3) interstadial (59–24 ka BP) correlates with global warming that promoted expansion of the spruce- and pine-dominated taiga. The new glacial advance during the late Last Glacial/Sartan stage (MIS 2), confined to the Polar and Northern Urals with localized ice caps, led to the formation of tundra-steppe and tundra-forests in the southern lowland and the mountain areas, respectively (Velichko 1993). The geographic distribution of glacial landforms and glacigenic deposits provides evidence of the Arctic ice expanding from the Kara Sea Basin along the western slopes of the Urals and possibly merging with some mountain piedmont glaciers (Mangerud et al. 2002, 2008). The eastern slopes of the Urals likely hosted an ice-free environment in view to an increased regional atmospheric aridity. Accelerated loess accumulation in the Fore-Ural area marks the onset of the full Last Glacial conditions with incorporating remains of large Pleistocene animals (*Mammuthus primigenius*, *Coelodonta antiquitatis*, *Equus* sp., *Bison priscus*) and small species typical of periglacial tundra-steppe (Yakhimovich et al. 1987). Fluvial formations on both sides of the Urals illustrate rich Late Pleistocene ecosystems with faunal communities of periglacial tundra-steppe (mammoth, woolly rhinoceros, horse, bison, reindeer, elk, saiga) with smaller open-steppe and semidesert taxa such as wolf, fox, hare, marmot, as well as rodents and other mammals indicative of mixed polar tundra-steppe biotopes. Permafrost limits at the end of the Pleistocene (the Allerød Warming) were still located at 55°N in the Trans-Urals/West Siberia (Velichko et al. 2002). Precipitation values during the late Last Glacial and the early Holocene (15–10 ka BP) amounted to c. 60–65% on the East European Plains and 80% in West Siberia comparing to the present-day values. The modern geographic distribution of particular biotopes in the broader territory of the Urals reflects the Holocene climate development.

Pleistocene Environments and Early Human Occupation

Interaction of the Pleistocene climatic variations with the regional relief modeling by the northern Arctic glaciations, interglacial sea transgressions, and stages of river erosion and sediment weathering attest to the complexity of the Quaternary history of the broader Ural area. During most of the Pleistocene, the North and Central Trans-Urals, sloping east from the central mountain range, were ice free. The bordering foothills and plains of West Siberia constituted parts of the periglacial super zone (Arkhipov 1999) and the place of mass accumulation of aeolian deposits transported from the ablation zone of the NE European-West Siberian ice sheets. The geographic and topographic configuration of the Urals, forming a natural gateway for the early human infiltration further east into the vast parklands and forest lowlands of Western Siberia, predisposed a long occupation history. The initial human inhabitation of the Ural territory, presumably from the northern Caucasus region and East European Plain, was a complex process governed by changing paleoecology conditions in response to the Pleistocene climate variations. Warm Middle Pleistocene interglacial conditions providing rich biotic resources of forest-parklands undoubtedly facilitated early human migrations further north and east along the Ural range via the major river systems (Volga, Kama, Pechora) draining the East European Plains. Mixed coniferous and broad-leaved forests with pine, birch, lime, elm, and beech formed a mosaic vegetation cover during the late Middle Pleistocene (MIS 9 and MIS 7) interglacials.

Presently the oldest-recorded (the Lower and Middle Paleolithic) sites are exposed along the Kama River banks along the western Ural foothills due to erosion of subaerial sediments

overlying relics of the Middle Pleistocene (35–60 m) fluvial terraces. The cultural material is represented by archaic core-and-flake stone industries (cores, retouched flakes, scrapers, and other tools) produced on cobbles from the gravelly alluvia (Fig. 3a). Fragmented animal bones with anthropogenic working and use attributes (flaking, splitting, retouching) indicate productive riverine valley occupation habitats and complex behavioral activities (Fig. 3b). The formal technological uniformity of these finds and their patterned geological contexts indicate a gradual and intensified peopling across the midlatitudes of Eurasia prior to the Last Interglacial (>130 ka BP) (Matyushin 1994; Chlachula 2010, 2017). Periglacial subarctic tundra-steppe and forest-tundra expanded during the late Middle Pleistocene (MIS 8 and MIS 6) glacial stages in the northeastern part of Europe (the Pechora Urals)

Urals: Paleolithic, Fig. 3 Illinsk Site (the Upper Kama Basin): (**a**) Stone tools from the Middle Pleistocene alluvia buried by 10 m of loess deposits. (**b**) Humanly flaked bones of fossil fauna (mammoth, woolly rhinoceros, Cervidae) found in association with the Paleolithic industry provide evidence of favorable interglacial natural environments in the parkland zone of the central Fore-Urals

over most of the extra-glacial territories hosting periglacial fauna (*Mammuthus primigenius*, *Coelodonta antiquitatis* Blum., *Rangifer tarandus*, *Bison* sp.). These prominent cold periods brought presumably a significant reduction of the former early human occupation areas.

The major climatic warming at the beginning of the Last Interglacial/MIS 5 (130 ka), recorded in the loess-paleosol sections from the East European Plain to southern Siberia, caused inundations and ground saturation of the formerly glaciated areas and thus temporarily impeded free movements of early humans. Increased continentality and MAT led to expansion of parkland steppe facilitating new migrations of the Middle Paleolithic (Neanderthal/early *Homo sapiens*) people (Fig. 4). High summer temperature (increased by c. 4–5 °C in respect to present values) and mean annual precipitation (by c. 100 mm) contributed to the northward distribution of southern taiga along both sides of the Urals by 500–700 km beyond the present limits (Velichko 1993). Pine-spruce-birch forests with oak, hornbeam, lime, hazel, and elm characterized the prevailing warm interglacial mosaic vegetation (MIS 5e, MIS 5c). Recession of human occupation is linked with the onset of the early Last Glacial stage (MIS 4, 74–59 ka BP) reducing the formerly inhabited areas of the periglacial steppe zone around the Southern Urals and repeatedly during the late Last Glacial stage (MIS 2, 24–12 ka BP). The most intensive late Middle/early Upper Paleolithic geographic expansion occurred during the mid-Last Glacial interstadial interval (MIS 3, 59–24 ka BP) reaching the northernmost regions of the Urals and the adjacent territories of Northern Europe and NW Siberia (Pavlov 1996; Pavlov et al. 2001). The progressive biological and cultural adaptation enabled to retain the new lands prior and shortly after the LGM. The Central Urals forming the free geographic passage connecting the East European Plain with the vast West Siberian territories most likely played a key role in this historical evolutionary process.

The Upper Paleolithic occupation of the Urals is principally associated with open-air sites in the western foothills and the cave complexes in the

Urals: Paleolithic, Fig. 4 Galyanskaya Site. Bifacial Middle (?) Paleolithic stone tools from an open-air site in the Tura River valley, a tributary of the Chusovaya valley, may represent the earliest cultural records found in the Central Ural region, including the "Neanderthal" Levallois stone-flaking technique. (Courtesy Yu. B. Serikov)

Urals: Paleolithic, Fig. 5 The Chusovaya River valley, Central Urals, with karstic limestone formations incorporating Late Pleistocene cultural records. The valley served as one of the main Paleolithic and Mesolithic migration corridors connecting the East European Plains and the West Siberian Lowland

Chusovaya River valley cutting E-W through the main Ural mountain range (Fig. 5). The multilayer sites (Bezymyannaya Cave, Kotel Cave, Kamen Dyrovatyy, Bolshoy Glukhoy) distributed in the karstic formation over a 200 km distance encompass a long record spanning from the Late Pleistocene (Middle Paleolithic) till the Iron Age (Fig. 6). Periglacial biotic niches possibly existed

Urals: Paleolithic, Fig. 6 Geographic distribution of the investigated Paleolithic cave sites in the Chusovaya River valley (central Urals): *1* Grot Dozhdevoy, *2* Grot Dyrovatyy (Cave 4), *3* Grot Dyrovatyy (Cave 5), *4* Grot Kirpichnyy, *5* Grot Kotel, *6* Grot Dyrovatye Rebra, *7* Grot Bolshoy Glukhoy

in the Chusovaya River tributaries (Koiva, Sylvitsa, Serebryanka) that may have allowed continuity of the local occupation throughout the Last Glacial Maximum (20–18 ka BP). A unique cultural (Late Pleistocene to Holocene) cultic place with >18,000 arrowheads made of various materials (stone, bone, and metal) originates from Kamen Dyrovatyy Cave, with the Upper Paleolithic level dated to 13,800 year BP. Other Central Ural cave sites interpreted as cultic in view to recorded archaeological cultural inventories (Kumyshanskaya Cave, Ignatievskaya Cave, Grot Zotinskyy, Kotel Cave) as well as those in the Southern Urals (Kapova Cave) (Matyushin 1994) suggest a high sociocultural and behavioral complexity (Fig. 12). In the latter mountain zone, spruce and pine taiga forests persisted until the onset of the Last Glacial (c. 22–21 ka BP). A certain regional cultural nonuniformity across the Ural territory manifested in the lithic industry composition may indicate differences in the regional environmental adaptations. The

taxonomic diversity of hunted fauna is particularly evident at the Final Paleolithic/Mesolithic sites, specializing on hunting reindeer and mammoth in the montane areas and the eastern lowlands, respectively (Serikov 1999, 2000; Kosintsev and Plasteeva 2015). A multifunctional character and a variety of particular activities are indicated by the broad repertoire of stone and bone tools, including "hacking" instruments, barbed harpoons, and arrowheads (Fig. 7). A microlithization and stone tool polishing in the Mesolithic complexes distributed across the Urals and West Siberia point to an adaptive adjustment and a diversification of exploitation of the Final Pleistocene/early Holocene environments.

In contrast to the forest settings of the central montane valleys, the eastern Ural foothills passing into the West Siberian Lowland hosted a variety of natural settings related to seasonally water-saturated taiga forests with braided river streams, lakes, and bogs. This vast and biotically very rich and diverse territory underwent a paleogeographical and paleoecological evolution reflecting large-scale environmental shifts, partly affected by the Arctic as well as the mountain Pleistocene glaciations. The stratigraphic positions of the mapped Pleistocene sites are determined by past geomorphic processes and biotic shifts in both the lowland and foothill areas with an absence of thick loess deposits that are present on the eastern slopes of the Urals. The Paleolithic in the Trans-Ural regions, predating the mid-Last Glacial, is poorly known contrary to the western regions of the Urals associated with open sites in the NE European periglacial belt (Pavlov 1996). The archaic character of the documented local (Paleolithic as well as Mesolithic) stone industries may reflect their expedient, time-transgressive character predetermined by raw material sources (Serikov 2000).

The easternmost limits of the Trans-Urals provide multiple lines of evidence of Paleolithic peopling of this geographically marginal and still poorly explored territory of West Siberia following the mid-Last Glacial warming (35–24 ka BP). A specific cultural entity represents the Upper Paleolithic complex of open-air sites in the Sosva River Basin on the periphery of the West Siberian Lowland (Fig. 8) contextually associated with massive concentrations of large Pleistocene fauna remains, previously interpreted as natural "mammoth cemeteries" known since the nineteenth century. Other fossil fauna with woolly rhinoceros, bison, horse, reindeer, and other animals characteristic of periglacial tundra-steppe together with small (bird and fish)

Urals: Paleolithic, Fig. 7 Dyrovatye Rebra Cave (the Chusovaya valley). Final Paleolithic "hacking" tools made of elk antlers

Urals: Paleolithic, Fig. 8 Erosion of the former Sosva River floodplain in the north-central Trans-Ural area delivers rich and partly humanly worked fossil faunal records attesting to biotically very productive Late/Final Pleistocene periglacial tundra-forest and tundra-steppe environments

species indicates a diversity of exploitation of the local Late Pleistocene natural resources and adaptation to subpolar periglacial environments (Chlachula and Serikov 2011). The skeletal remains from the occupation localities suggest both active hunting and anthropogenic scavenging practices during the Last Glacial (with radiocarbon dates of c. 25–12 ka BP). Human behavioral activities at the key site Gari I are also documented by circular concentrations of mammoth and rhinoceros bones (including complete sculls, large bones, and tusk fragments), some of them artificially modified, reminding primitive dwelling structures known in the Upper Paleolithic from the East European Plains. The geological context of the well-preserved fossil records, sealed in cryogenically distorted alluvial deposits of the former meandering Sosva River, indicates complex taphonomic histories of the occupation sites buried in cold periglacial swampy-riverine settings (Figs. 9 and 10). The paleontological records show an extraordinary biotic potential of the Pleistocene periglacial West Siberian steppe marginally interspersed by the eastern Ural foothill ecosystems. The dominant exploitation of mammoth (98.5%) corroborates the faunal compositions from other Upper Paleolithic sites on both sides of the Urals (Byzovaya Cave, Mamontova Kurya in the Pechora Basin; Volchiya Griva in West Siberia)

Urals: Paleolithic, Fig. 9 Rychkova Site (the Sosva River Basin). A mammoth tusk buried in the Late Pleistocene overbank clay deposits. *Mammuthus primigenius* is the most-represented species in the Late Pleistocene fossil fauna assemblages of the Trans-Ural area

(Pavlov 1996; Petrin 1986; Savel'eva 1997; Svendsen and Pavlov 2003; Zenin 2002).

The adjacent West Siberian Lowland is assumed to have been colonized after the Last Glacial Maximum at c. 17–15 ka BP in view of the extreme environmental conditions (a high climate continentality and natural water/stream barriers). The north Trans-Ural and probably the Siberian Arctic regions remained largely ice free even during the LGM, and except for surface-saturated and frozen boggy lowlands, there were no major natural obstacles for free movement of Paleolithic groups further east into NW Siberia

Urals: Paleolithic, Fig. 10 Gari Site I (the Sosva River Basin). The Upper Paleolithic stone industry (nuclei, scrapers, burins, retouched blades, and flakes made from local alluvial gravels) together with utilization of skeletal megafauna remains (10 – a mammoth tusk flake) indicates a successful human adaptation to the Last Glacial ecosystems of the Trans-Urals and the adjacent West Siberia

prior and after that time interval. Fossil fauna finds display a major biotic potential of these territories. The latitudinal zonal differentiation of the Last Glacial ecosystems of the Urals from the Arctic coast to the Black/Caspian Sea was likely more uniform, largely covered by periglacial tundra-steppe in contrast to the more mosaic interglacial parkland landscapes facilitating a free migration of fauna as well as the Upper Paleolithic groups particularly within the foothill corridors. Regional paleoenvironmental deviations, differing from the overall territorial biogeographic and climatic pattern, may have played a significant role in the process of early prehistoric peopling of the northern regions.

International Perspectives

The present state of the Paleolithic research in the Urals provides evidence of an active process of the early peopling in this strategic geographical territory on the crossroads of Europe and North Asia. The contextual geology and paleoecology records from the investigated archaeological sites and stratified geological sections point to pronounced environmental dynamics and landscape transformations triggered by past climate change as well as geomorphic processes over the mountain as well as foothill areas. The Pleistocene climatic cycles regulated spatial and temporal movements of early humans from the southeastern regions of the European continent as well as the subsequent expansion onto the bordering North and West Siberia.

The first well-manifested occupation, particularly in the western Fore-Ural foothill areas adjacent to the East European Plains, occurred during the Middle Pleistocene interglacials, presumably the Likhvin Interglacial complex (450–360 ka BP) being the warmest and most favorable climatic interval for the last 0.5 Ma years (MAT by c. 4–5 °C above the present values). Abundant expedient core-and-flake stone industries together with anthropogenically worked fossil fauna osteological materials indicate productive riverine valley habitats of the Kama River Basin with mixed (spruce-fir and oak-linden-elm-hornbeam) parklands. Except for the Southern Ural regions, persistence of inhabitation in glacial stages within extremely cold polar tundra-steppe environments predetermines use of fire, but this is unlikely at the time of the most extensive continental Pleistocene glaciations of northern Eurasia reaching the Central Ural limits.

The next stage of the Pleistocene peopling of the Urals is linked to the Middle Paleolithic (Neanderthal) expansion during the Last Interglacial/MIS 5 (130–74 ka BP). The climatic optimum (with MAT 1–3 °C above the present values) promoted mosaic vegetation in the particular geographical zones and topographic settings with mixed pine-spruce-birch forests enriched by broad-leaf taxa (oak, hornbeam, lime, hazel, and elm) in the montane areas, and open-parkland steppe in the lowlands. During the cold Last Interglacial stages (MIS 5d, 5b), these ecosystems were replaced by tundra-forest and periglacial tundra-steppe, respectively. The main river valleys cutting the mountain range with rich rocky material for stone tool production as well as diverse biotic resources were likely occupied repeatedly at various Last Interglacial intervals. Cultural finds are absent from the climatically harsh early Last Glacial (MIS 4).

The following Late Paleolithic dispersal represents a most distinctive cultural marker recorded throughout the Ural territory associated with the climatic amelioration during the mid-Last Glacial stage/MIS 3 (59–24 ka BP). This environmentally favorable time interval with a climatic optimum at c. 31 ka BP correlates with the progressive spatial expansion further north along the western as well as the eastern Ural slopes reaching the ice-free subpolar limits as witnessed by the cultural records from the Upper Pechora Basin and the Siberian Arctic in the biotically productive periglacial tundra-steppe environments. Geographical shifts of the early Late Paleolithic milieu into the marginal mountain areas across the Central Urals into the adjoining West Siberian Lowland are likely to have occurred still during the warmer interstadials prior to the LGM. The Chusovaya River valley transecting the central mountain range was one of the main corridors for Pleistocene fauna migrations from the East European

Plain into West Siberia (Fig. 11). The formal diversity of blade-dominated lithic industries suggests regionally specific cultural environmental adaptations.

Probably only isolated human populations occupied the Central Urals around the Last Glacial Maximum/LGM (24–19 ka BP) contrary to the biologically more productive periglacial tundra-steppe in the southern Fore- and the Trans-Ural regions. Yet, the radiocarbon dates (23–19 cal ka) from the archaeological strata of the Medvezhia Cave provide evidence that humans were present along the Northern Urals close to the LGM (Svendsen et al. 2010). Milder microclimate conditions in the foothills with a higher diversity of biotic resources of the transient montane-taiga and steppe fauna communities predisposed the periodic occupation recorded in the Central and Southern Ural karstic areas during the Last Glacial (24–12 ka BP).(Danukalova and Yakovlev 2006). The dominance of woolly mammoth in the lowland parkland (tundra-)steppes and horse/reindeer in the mountain areas illustrates the pattern of animal resource exploitation (Fig. 12). The later

progressive regional cultural development is manifested by the appearance of locally heterogeneous Mesolithic complexes in response to climate warming and associated environmental transformations at the end of the Pleistocene.

The Trans-Ural Upper Paleolithic complex, best documented in the Sosva-Tavda River Basins, represents a specific cultural entity based on utilization of the Pleistocene fauna attesting to a particular behavioral adjustment to the Last Glacial tundra-steppe/tundra-forest environments with active hunting as well as anthropogenic "scavenging" of naturally deceased animals (particularly of mammoth). The multifunctional use of skeletal remains for dwelling structures, tools, and artwork also encountered in the contemporaneous cultures of the Upper Kama and the Upper Pechora Basins along the NW Urals correlates with the climax of the Paleolithic evolution in the periglacial zone of the mid- and high-latitude Eurasia. Overall, the Last Glacial climate fluctuations and the associated shifts in natural habitats preconditioned the intensity and timing of the Paleolithic settlement of these marginal and geographically rather extensive areas. The initial human colonizations along the Ural Mountains into the Arctic clearly took place at the latest in the climatically moderate mid-Last Glacial (MIS 3) interstadial stage (55–24 ka BP) when only small glaciers covered the nearby mountain ranges. The southern and central Ural regions were inhabited much earlier.

Future Directions

The scientific importance of the Ural Paleolithic studies lies in the documentation of the earliest prehistoric migration processes, the adaptation strategies, and the cultural exchanges between Eastern Europe and West Siberia. Complex paleoenvironmental and climatic multiproxy data from the stratified geological sections coupled with cultural archives of the presently investigated as well as perspective archaeological localities will contribute significantly to a more comprehensive understanding on the overall trajectories of the Paleolithic and Mesolithic occupation of north-central Eurasia. Detailing the single-site chronologies and geological and paleoecology contexts should be in the focus of the following geoarchaeological studies. Systematic field reconnaissance in the upper reaches of the Chusovaya River and its tributaries (Koiva, Sylvitsa, Serebryanka) together with the foothill areas of the Northern Urals may provide new evidence on the earliest human settlement from these still poorly studied geographical regions. Application of the integrated Quaternary geology and geoarchaeology field research approach and laboratory analytical methods should constitute a working framework of the future Paleolithic investigations particularly in the marginally mapped formerly glaciated areas of the Northern and Polar Urals, the Fore-Urals loess formations, as well as of cave sites in the central and southern regions. The new results will complete the present culture-historical mosaic of the early human inhabitation, particularly in the largely unexplored northern territories.

Urartu, Archaeology of

Juan Christian Rodriguez Bobadilla
Escuela Nacional de Antropología e Historia, Mexico City, Mexico

Introduction

Urartu was an Iron Age kingdom that flourished between the ninth and the seventh centuries BCE in the northern regions of the Ancient Near East, stretching across portions of the modern nations of Turkey, Armenia, Iran, and a small part of northeastern Iraq (Dan 2010).

Celebrated as one of Assyria's uttermost rivals (and for a time the most powerful state in the Ancient Near East), this political entity has been the object of numerous studies in the past 15 decades (Piotrovsky 1969; Barnett 1982; Lindsay and Smith 2006). Over this time, the Urartian material culture assemblage has proven to be very characteristic and distinguishable within the archaeological record in the Ancient Near East (Zimansky 1995a). This entry provides a general historical overview of the Kingdom of Urartu while focusing on the development of Urartian studies and Urartian archaeology as well as on Urartian material cultural assemblage.

Definition

Urartu, Bianili, and Nairi

The name Urartu (which is the same as Ararat present in modern bible or the word "*rrt*" in original Hebrew) comes from the Assyrian language and was employed by the Assyrians to refer both to a specific region lying northeast from Assyria (and also written as "Uruatri") and to a particular political entity (comprised across sections of modern-day Turkey, Armenia, northern Iraq, and northeastern Iran) that was conformed around 830 BCE and disappeared in the seventh century. A wide array of the information we currently possess on Urartu comes from Assyrian texts and inscriptions, and scholars often employ the term "Urartian" in order to denominate both the language and the culture of the kingdom in question. However it is important to notice that Urartian kings did not refer to their land as Urartu but as Bianili. Currently, scholars often refer to this latter as Urartu/Bianili. Therefore, in order to avoid confusions, it is necessary to set this distinction straight. In addition to this, Assyrian sources also mention the term "Nairi" which also is geographical in nature and refers to several minor kingdoms subdued by the Assyrian King Tiglath-Pileser I at the end of the eleventh century BCE. Nairi is also an important term since King Sarduri I left an inscription (which is actually the first inscription that can be attributed to a king of Urartu/Bianili) calling his kingdom "Nairi" (Zimansky and Sagona 2009).

Key Issues

A Historical Overview of Urartu and Urartu/Bianili

Although the region in which the Kingdom of Urartu/Bianili was comprised has a long history, this section focuses mostly on the history of the political entity that was conformed between the ninth and the seventh century BCE.

There is agreement among scholars that the region was already inhabited by the sixth millennium BCE, and the presence of third millennium occupations has been reported in the Lake Urmia area (Zimansky and Sagona 2009). The first written records that mention the region in question were written by the Hittites in the second millennium. In them, Hittite kings mention the presence of two different kingdoms named Azzi and Khayasha. Later on, the area fell under the influence of the Mittani, yet by the thirteenth century BCE, the region slipped out of Mittanian control and was incorporated into the Assyrian sphere of influence as multiple campaigns were launched by

different Assyrian kings who sought to dominate and excerpt tribute from this area (Barnett 1982). These campaigns were amply recorded in Assyrian texts and in them are not only clues to the type of relationships Assyrians held with those societies living in the area of Urartu but also the first traces for building the political history of Urartu/Bianili (Barnett 1982; Radner 2011). For example, the Assyrian King Shalmaneser I refers to these lands as "Uruatri" and mentions the presence of at least eight different kingdoms (Piotrovsky 1969; Barnett 1982; Zimansky and Sagona 2009). As for the Kingdom of Urartu/Bianili, its political history begins in the latter part of the first millennium. Smith (1999) subdivides it into three periods that he denotes as formative, imperial, and reconstruction, and this division is based upon historical records and the physical landscapes produced by state authorities. The formative period (c. 1300–850) is not well understood and the archaeological evidence is scarce especially in the eastern Anatolian region.

In the mid-ninth century BCE, Urartian kings began conquering rival polities in an area that ranges from the area of Lake Urmia in the southeast to the headwaters of the Euphrates in the northwest, as well as the incorporation of the Sevan Basin in the Shirak Plain. This program of military campaigns represents the imperial period. Another important characteristic of this period includes a program for the construction of massive fortresses in the Ararat area under the auspices of Urartian King Argishti I. This period of imperial expansion was brought to an end in the late eight century when Assyrian armies under the King Sargon II advanced north while at the same time Cimmerians irrupted in Urartu/Bianili's northern border. Urartian King Rusa I was able to overcome the critical situation. He inflicted a defeat to the Cimmerians and Assyrian armies eventually withdrew to their homeland (Piotrovsky 1969; Barnett 1982; Smith 1999; Zimansky and Sagona 2009). In addition upheavals and challenges to the Urartian dynastic power arose. In the aftermath of this situation, the Kingdom of Urartu/Bianili managed to survive, and Rusa I was able to regain the political control of the kingdom and suffocated the rebellions. However Urartu/Bianili was never able to experience another expansionist era.

The reconstruction period follows immediately after the imperial period. This is not as rich as the previous period in historical records, yet the archaeological evidence is quite substantial. Among other things, this evidence permits scholars to suggest that the Urartian state authority was fully reestablished and that Urartu/Bianili once again challenged Assyrian power in the highlands. Further, Urartian kings were able to recover control over much of the territories lost during the end of the imperial period (Smith 1999). The reign of King Rusa II represents the zenith of this period, and thanks to a series of foundational inscriptions, the construction of a series of massive fortresses can be directly attributed to him (Zimansky 1995a; Smith 1999). The information regarding the successors of Rusa II is unclear, and by the early sixth century BCE, the Kingdom of Urartu/Bianili was once again immersed in a series of crises. As a matter of fact, it has been suggested that Rusa II's intensive program of massive fortress building was a direct result of the overwhelming pressure nomads such as Cimmerians and Scythians were exercising on Urartu/Bianili at the time, and this fact has also been signaled as a probable cause of both the Urartian and Assyrian collapses (Çilingiroğlu and Salvini 2001). As for the exact time of when Urartu/Bianili collapsed, Piotrovsky (1969) dated it as happening either in 585 or 580 BCE based upon biblical dates. However, Sebastian Kroll (1984), as well as other scholars, thinks this date is uncertain and disagrees with such a long chronology. In any case by the late sixth century BCE, references to the Kingdom of Urartu/Bianili disappear completely from written records.

Urartian Material Culture Assemblage

Urartian material culture assemblage is important because it allows scholars to trace the spread of the Kingdom of Urartu/Bianili through the presence of distinctive styles of architecture, art, and pottery. This is unmistakably distinguishable to the degree as Zimansky (1995a, 103) states that "these are defined with such precision that things are not Urartian by degrees or with qualifications –

they either are so, or are not." However, despite its condition of uniqueness and uniformity, the same author points out that it is important to remember that the Urartian material culture studied by archaeologists and linguists is mostly a governmental production representing the elites rather than a broad segment of the population (Zimansky 1995a). For instance, most of the Urartian archaeological efforts have been oriented toward the excavation of fortresses (Piotrovsky 1969), waterworks (Burney 1972; Garbrecht 1980), and royal tombs (Barnett 1963). Only recently archaeologists have started investigating residential areas nearby the fortresses as is the case of Ayanis (Stone and Zymansky 2001) and Bastam (Kleiss 1980). Since Urartian material culture assemblage is displayed in a wide array of categories, this section will deal only with the most general of them. One focus is architecture and another is pottery and metalwork.

Urartian architecture is represented by diverse levels ranging from domestic to state sponsored. When it comes to the latter, architecture is both massive and impressive. This entry focuses on the best examples of state-sponsored architecture which are fortresses and waterworks.

Urartian architects excelled at constructing fortresses and often choose strategic locations at natural eminences where fertile ground, agriculturally productive land, and communication routes could be overlooked. Fortresses were emplaced in carefully selected locations allowing defensibility but avoiding isolation from the rest of the countryside (Zimansky 1995a). Urartian fortresses were completely surrounded by walls, and these conformed a perimeter whose function was to protect multiple storage magazines, arsenals, and administrative facilities. Perhaps the most outstanding characteristic of Urartian defensive architecture is the outer walls. These walls were buttressed, and sometimes, at the places when angles changed, major towers were built. Urartian fortress walls were so massive that more than often exceed 4 m of thickness, and based upon some art depictions, it has been suggested that they were several meters tall and topped with crenellations (Zimansky and Sagona 2009).

These types of structures belong both to the Imperial and to the reconstruction period. King Argishti I built several fortresses in the Sevan area, while King Rusa II built what are considered the most impressive examples of fortresses during the reconstruction period. Toprakkale (or Rusahinili as it was originally known to Urartians) is a fortress in the outskirts of the modern city of Van. Its importance lies in the fact that its citadel rock was the political center of the empire. This last is located 5 km away from Toprakkale and was placed next to the ancient city of Tuspa which was the capital city of Urartu/Bianili. Most of the artifacts found at Toprakkale are dated to the seventh century BCE, and only very few items belong to the eight century BCE (Zimansky 1995b). In Turkey in the shore of Lake Van, the fortress of Ayanis is found. Archaeological work at the site began in the late 1980s, and as a result of the discovery of some inscriptions in a temple, scholars now know this fortress was named Rusahinili Eidurukai or the city of Rusa in front of Mount Eiduru setting a distinction from Toprakkale (Çilingiroğlu and Salvini 2001).

Another site, Karmir Blur (or the ancient city of Teisheba), lies next to modern Erevan in the Republic of Armenia. Karmir Blur is rich in well-preserved archaeological remains since it was violently destroyed resulting in an outstanding preservation of the archaeological contexts. Archaeologists have excavated the complete ground plan of the citadel, and the function of all rooms found within the citadel has been determined due to the fortuitous finding of the inventories (Zimansky 1995b).

Another fortress built by Rusa II that has been extensively studied by archaeologists is Bastam (Rusai-URU.TUR or Rusa's small city). Discovered in the 1960s by a German archaeological team, it remains as one of Urartu/Bianili's largest fortresses built. In this case the fortifications extend from the plain level to the summit of the hill, and just as in Karmir Blur, multiple magazines for storage have been found. Along with the architectural remains of the wall's stone foundations, archaeologists have uncovered evidence for royal administrative practices such as bullae with imprints of Rusa II's seal and tablets (Kleiss 1980; Zimansky 1995b).

Urartian architects excelled at projects other than fortresses. Reservoirs, terracing, and irrigation works are found through the entire Urartian region (Burney 1972), and as hydrotechnical installations, they are remarkable, elaborate, and well-planned water supply systems (Garbrecht 1980). Perhaps the finest example is the water supply system that provided Tuspa with freshwater, both for daily consumption and for irrigation activities. This 56 km massive waterwork built by King Menua initially brought freshwater to the royal capital at the citadel of Van (Van Kale), and later it was extended by either King Rusa I or Rusa II to supply Toprakkale from a spring located in the neighboring valley of Engil Cayi river (Garbrecht 1980). Besides its importance as a massive construction, the Menua Canal (which is first of several sections of the hydrotechnical system) has been securely dated to the reign of this king (805–785 BCE) due to a series of inscriptions that are found along the aqueduct. This is not only a rare but a fortunate finding for archaeologists since waterworks often lack of archaeological evidence – such as pottery or coins – which allows secure and precise dating (Garbrecht 1980).

Ceramic traditions that precede the presence of Urartu/Bianili as a state are just as difficult to identify as those traditions that immediately follow the kingdom's temporality. As an exception, the ribbed buff ware bowl has been described as an Early Iron Age tradition that continues well into time of Urartu/Bianili's development in the first half of the first millennium BCE. On the other hand, Urartu/Bianili's pottery is very distinctive, especially the kind that is associated with state activities. Kroll (1976) argues that ceramics at 95% of Urartian sites consist of simple, undecorated brown and buff wares. In the case of this simple ceramics, the boundaries of the state cannot be correlated with its distribution (Zimansky and Sagona 2009). Instead, wares associated to the state are much clearer to identify and constitute the core of the Urartian pottery (Zimansky 1995b). "Toprakkale Ware" and pithoi represent examples to illustrate this point. The "Toprakkale Ware" was originally labeled as such by Charles Burney (1957) and can be considered a diagnostic type since it is distinguishable both by color and finishing being red and highly burnished. Zimansky and Sagona (2009) mention that as a result of neutron activation analysis, scholars now know that this pottery was locally made even though it looks the same throughout the extension of Urartu/Bianili and that its essential function was wine and food serving since trefoil-shaped jugs and slightly incurving rimmed plates are the most common forms associated with this type.

The previous section indicated that fortresses included storage facilities. Within these, rows of enormous jars or *pithoi* have been found buried up to their shoulders in the contexts of every major citadel. Because of its shape and size, it has been long argued that liquids were stored in them (Zimansky and Sagona 2009). At Toprakkale, Piotrovsky (1969) calculated the total storage volume at a little over 34,000 l (9,000 gal). However, Wartke (1993) has argued that the storing capacity was quite more substantial estimating 400,000 l. In the opinion of Zimansky and Sagona (2009), this last figure looks more correct.

Finally, metalwork is also an important component of the cultural assemblage of Urartu/Bianili. Metalwork in Urartu is mostly characterized by the production of bronze artifacts such as cauldrons, figurines, shields, helmets, horse trappings, belts, bowls, and plaques. According to Zimansky (1995a), metalwork production is closely associated with the Urartian state since many of these artifacts bear inscriptions that mention Urartian kings. Despite the importance of Urartian metalwork as a component of the Urartian material culture, heavy criticizing has been raised around the way metal artifacts have been studied archaeologically. Muscarela (2006) argues that several problems arise when archaeologists are unaware of crucial details approach the material. Among them he points to the fact that most of the metal artifacts are the product of looting and plunder carried out for many decades, thus resulting in unprovenienced material, and he adds that this is problematic since omitting this fact may lead to subjective conclusions. One of

the publications discussed by the same author is *Urartian Art and Artifacts* (Azarpay 1968) which according to the author focuses mostly on excavated material although fails to discuss the full corpus. Another important publication brought up in Muscarela's discussion is *Urartu: A Metalworking Center* (Merhav 1991) which shows wonderful illustrations of the full repertory of metal artifacts and compiles excellent scholarly essays written by authorities in Urartian archaeology. The work contains only a handful of the hundreds of pieces displayed, and only some come from actual excavations, while the vast majority lacks from provenience and comes from private collections.

Future Directions

There are many things unknown about Urartu/Bianili and research along specific lines is necessary. In the first place as Zimansky (1995b) points out, Urartian archaeology has been oriented toward fortified sites under state direct control leaving out of the map wider sectors of the Urartian population leading to a subjective homogeneity of the Urartian society. Some efforts have been done in this sense (Stone and Zymansky 2001), yet there is so much more that we need to know about the Urartian society that did not belong to the upper strata. On the other hand, Urartian elites cannot be completely ruled out of the question, and important research lines have been pursued in terms of how they exercised the power and contemplated themselves. Smith's work on political landscapes represents a thriving effort to understand how Urartian elites constructed spaces to exercise their power. In a similar line, Tanyeri-Erdemir (2006) has analyzed Urartian imperial art and architecture focusing on how material culture may have been used by King Rusa II as an active component in the modification, renewal, and reproduction of his rule. In sum, Urartian archaeology offers young scholars not only an open invitation to pursue research careers but a wide variety of subjects that still need to be explored.

Urban Archaeology

Tadhg O'Keeffe
School of Archaeology, University College Dublin, Dublin, Republic of Ireland

Brief Definition of the Topic

The phrase urban archaeology is used to refer to the study of archaeology *in* towns or cities or *of* towns or cities. The former, which is a rather narrow definition, describes the practice of archaeology in urban places, particularly "living" urban places (as distinct from towns and cities which were abandoned in the past and are ruinous). Distinguishing it from other branches of the discipline are the particular challenges posed by working in such contexts: excavation is usually in response to development – or redevelopment, more frequently – rather than research-driven, so the locations of sites for excavation and the areal sizes of those sites are determined by the agencies of development; the timetables are often restricted; the stratigraphies are usually very deep, even in cities of modern origin; and preservation is generally by record only. Urban archaeology thus defined is most commonly practiced in countries where legislation protects potential archaeological heritage from destruction by infrastructural development without prior investigation and where the archaeological profession is large enough to accommodate teams who specialize in working in these environments. Such legislation varies from country to country. So too does the view of what constitutes an urban-archaeological heritage worthy of physical protection (in the case of standing buildings) or preservation by record (in the case of buried structures and deposits): the importance of archaeology of pre-1800 date is uncontested everywhere, but the protection afforded to nineteenth- and (especially) twentieth-century archaeologies is rather more hit and miss, although the development of archaeological research into the contemporary world is currently changing attitudes to the most recent past. There is now a body of literature dedicated to the nature of urban-archaeological practice and, closely related to it, a corpus of publications and "grey literature" pertaining to urban-archaeological strategies and policies. This archaeology-as-praxis definition is a development of recent decades, reflecting on the one hand the great explosion of infrastructural development in urban places in the second half of the twentieth century, particularly post-WWII in certain parts of the world, and on the other the fact that research into the medieval and early modern pasts – the period of foundation of so many "living" towns and cities – was itself sporadic and poorly coordinated until the 1960s.

The second, broader definition presents urban archaeology as the archaeological understanding of urban spaces and urban lives, regardless of their location or date. It is, in other words, the

archaeology of *urbanism* as a phenomenon. It draws quite disparate studies – from, say, the study of prehistoric agricultural nucleations in Mesopotamia to the study of nineteenth-century slums and red-light districts in Australia and North America, for example – into the same net, although it has long been the case that histories of urbanism through time tend to be written by geographers and "urban historians" rather than by archaeologists. Most of the research on urbanism in our discipline is focused on understanding the patterns and processes of urban development in shorter time periods and in specific places: thus, for example, there is a voluminous literature pertaining to, for example, urbanism and ancient state formation, colonial towns in the Americas, and Viking-age towns in Europe, while there is an even greater volume concerned with the archaeologies of individual cities.

The distinction between the two definitions of urban archaeology is a fine one, since the purpose of all archaeological intervention in towns and cities, even in rescue-archaeology situations, is to inform our understanding of them. Indeed, published studies of individual urban places not only make central use of data from development-instigated archaeological excavations but are usually precipitated by such excavations. In any case, whatever the specific motivations for archaeological research, studies of individual cities – London, Annapolis, and Melbourne, to name three obvious ones – have been profoundly influential in the side-by-side development of archaeological praxis and archaeological thought.

The meaning or meanings of the term "urban" have, of course, long exercised scholarly minds, not only in archaeology but also in both closely cognate and distantly cognate disciplines too (e.g., geography and sociology, respectively). While debates about terminology often seem peripheral to the serious business of research, terminology is important because the words we use reflect and shape how we think. As an adjective, it is generally agreed across disciplines that "urban" possesses spatial, functional, and social meanings and that these meanings are bound up in each other.

In terms of space, first of all, urban connotes a place of densely concentrated population relative to its surrounding "countryside," with, *critically*, one being defined in contradistinction to the other in every particular instance. The terms "town" and "city" have historical resonances, but the adjective "urban" usefully bypasses the problems raised by the inconsistencies in their usage from one country (even region) to another; "village," however, is universally taken to connote a settlement too small to be regarded as "urban." The measurement of scale appropriate to the definition is not merely areal – the size of a settlement, in other words. Spatial connectivity is critical too: urban places are not merely central places in particular localities but connect to other urban places, allowing greater flows of people, goods, and ideas than are possible in places of dispersed settlement.

Such networks of connectivity bring us to the second definition. Urban places differ from rural places in their functions, and archaeology has contributed hugely to our understanding of those differences. Towns and cities are places of secondary (manufacturing) and tertiary (trade and service) industries and are capable of such specialization not simply because they are relatively large and populous. Rather, it is because they possess symbiotic relationships with rural places and their primary (food-generating) industries *and* are connected to other, similarly specializing, urban places. Archaeology, uniquely, locates the sites and products of such specialization in individual urban settings, illuminates the networks of connectivity which help to explain those products, and, perhaps most critically, reveals the social matrices in which the activities and patterns of production and service provision are located.

This brings us to the third understanding of "urban": its role as a descriptor of society, or more accurately of social relations, in places where the density of population in itself creates for all inhabitants very particular challenges of socio-spatial negotiation. Town and cities, particularly the latter insofar as that word describes very large settlements, are places where power structures are often overtly expressed in planning, architecture, and commerce and where space is contested according to wealth, class, ethnicity, and other forms of identity. Archaeological research on urban places has moved away in recent years from the mere

documentation of the physical heritage to sophisticated social analyses of urban spaces and materialities, a development spearheaded by work on modern (eighteenth-century and later) rather than medieval and more ancient cities.

Looking to the future, urban archaeology continues to face three particular challenges. First, the decades of growth that preceded the recent global economic crash generated in many parts of the world a huge corpus of material from urban sites. Much of this still needs processing. How do we achieve a balance between the storage and recording of data, both of which are time-consuming and expensive, and the generation of meaningful narratives about urban life? Second, given the speed with which urban places change character, even in a global recession, what constitutes urban heritage and what should be protected from alteration? Whose opinions should be solicited in making such decisions? To what extent should the emphasis shift from individual structures in cities to areas in cities and to the landscapes of parts of cities? Third, as archaeological interpretation becomes more sophisticated, there is a need for the discipline to engage more directly with other disciplines with research interests in urbanism. Thirty years ago, Clack and Haselgrove observed that "archaeologists still have no clear idea of what they are trying to contribute to urban studies." While much has changed, the discipline remains more marginal within the larger urban-studies research cluster than it should be given its data-collecting potential and its rich intellectual tradition.

Urban Archaeology at Five Points

Rebecca Yamin
John Milner Associates, Inc., West Chester, PA, USA

Introduction

The construction of a new federal courthouse at Foley Square in Lower Manhattan, New York City, by the General Services Administration (GSA) required a cultural resources investigation as stipulated in Section 106 of the National Historic Preservation Act (amended). The

Rebecca Yamin has retired

proposed location of the courthouse was on a block that was once part of the infamous Five Points, a neighborhood known as New York City's most notorious, nineteenth-century slum. Historical research conducted by Historic Conservation and Interpretation (HCI), Inc., a New Jersey firm headed by the late Ed Rutsch, recommended archaeological testing and excavation before construction of the building began. HCI's report, which was done under contract to Edwards and Kelsey, the engineers for the project, made it clear that any intact remains of the Five Points had the potential to provide a less biased picture of life in the neighborhood than the picture drawn by the yellow journalism of the day.

Key Issues/Current Debates/Future Directions/Examples

Before the project began, the site was being used as a parking lot. As is often the case in large cities in the United States, the only open land available for new development is open because buildings that once stood there have been taken down in order to create space for parking. The Courthouse Block was once lined with tenements that faced four streets: Pearl, Park, Chatham, and Baxter. The name, Five Points, derived from the intersection of two of those streets – Baxter and Park – with Worth Street, thus creating five points that emptied into an open area. A lithograph of that open area, dating to 1855, has become the iconic image of Five Points (Fig. 1) and was, in great part, the basis for the set of Martin Scorsese's *Gangs of New York* (2002), a movie based on a book of the same name, published in 1927.

A *project design* provided the program for the documentary research, survey, and excavation of the site, and its analysis and publication. When the tenements were taken down in the 1960s, their foundations including basements were left in place and covered with about 10 ft of fill. The site area included 14 historic lots, and excavation began with the mechanical removal of the fill that covered the basement walls and former

Urban Archaeology at Five Points, Fig. 1 Lithograph of Five Points in 1855 (New York State census). (Image: Valentine's Manual, 1855)

backyard areas on those lots. Once exposed, the building outlines were compared to a series of fire insurance maps that showed the changing configuration of each lot over time. In addition to the configuration of the structures, the maps, in this case by William Perris, include information on building material, use, and condition. The exposed walls were cleaned by hand (with shovels and trowels), and former backyard areas were cleared in order to locate structural features.

A total of 54 *features* were exposed including privies, cesspools, water closets, sumps, trash pits, at least one cistern, a possible ice pit, and a single bake oven. All were measured and mapped (Fig. 2), but only 22 were excavated. The sample included backyard features on lots facing all four street fronts. Features were generally bisected, one-half excavated *stratigraphically*, a profile drawn, and then the second-half was excavated. Catalog (context) numbers were assigned arbitrarily to each provenience (findspot, layer, or *context*) that was removed separately, and all artifacts were bagged by context. With a few exceptions, features were photographed and tied into one of 23 vertical datum points that were located throughout the site area. A few additional excavation units were used to sample the fill that had been deposited before the block was developed for residential use in the late eighteenth–early nineteenth century and to examine underlying strata that were believed to relate to the tanyards that were present on the block before that development.

Stratification diagrams were used to model the sequence of contexts and features and deduce phases of occupation – analytical units

Urban Archaeology at Five Points, Fig. 2 Plan of excavated area

or AU. Specialists in ceramics, glass, clay pipes, and other objects – together with architectural and faunal remains – used these tentative AUs as an initial guide to grouping artifacts. An effort was made to have all analysts working on, or at least beginning, features at the same time in order to maximize communication. AUs were refined based on cross-mending data, especially from the ceramics, and shared with other analysts. Terminus post quem dates (TPQs) were determined from each artifact category and compared to census and directory data which was being collected by a team of historians at the same time. Artifact and primary historical information were entered into a computerized database, which was available to everyone working on the project. Conservation of fragile materials was conducted in the same laboratory with the artifact analysis. Floral and parasitological analyses were conducted by consultants located elsewhere.

The collaborative approach to analysis provided a stimulating environment in which to consider the research questions posed in the research design and to generate new ones. Artifact analysts used their data, sometimes alone and sometimes in combination with other data, to address predefined general research areas: e.g., family and neighborhood life, work and industry, health and hygiene, the construction of the "slum," and working-class life. In addition to the resulting technical papers, the six-volume report includes a narrative history along with vignettes based on the archaeology, the primary documentary data, an illustrated compendium of smoking pipes, an artifact inventory, and a volume covering conservation (Yamin 2000).

The artifacts found in the features provided new insights into everyday life at Five Points. Feature B on Lot 6, for instance, included two sets of everyday dishes, a cut glass decanter and wine glasses, olive oil bottle seals, and lead seals with Hebrew letters on them that had belonged to a Jewish family named Goldberg who lived on the Pearl Street lot in the 1830s. Their food remains suggested they kept kosher and a book on New York City's early Jewish community listed a synagogue at that address, Harris Goldberg, sexton. A large cesspool on the same lot (Feature J) included artifacts associated with a tenement built in 1848 to house newly arrived Irish immigrants. The artifacts revealed evidence of people striving for respectability. They were not well-off, but they ate better than they had at home in Ireland and had dinner and tea wares imported from Staffordshire. A privy belonging to a brothel was found on the other side of the site (Lot 43 on the figure) that included two classes of artifacts – some that probably related to entertaining clients (a porcelain tea and coffee set, many wine bottles, lighting fixtures, fancily decorated smoking pipes, the remains of seafood snacks) and others relating to the private lives of prostitutes (the contents of a sewing box, female urinals, bird cage watering devices, children's toys, and china). The brothel was in the center of what was New York City's first garment district, and privies associated with the German and Polish tailors and second-hand clothing dealers who worked there were also excavated. There were thousands of straight pins – some still tucked in paper, fasteners, twill tape, buttons, and thimbles, some personalized and some specially made for tailors without tops. The picture that emerges of Five Points from the archaeology is not a generic picture of a slum. It was a vibrant, multiethnic neighborhood where various immigrant groups got their start-up in the economic ladder in their new homes.

Urban Archaeology in Twenty-First Century Perspective

Rebecca Yamin
John Milner Associates, Inc., West Chester, PA, USA

Introduction and Definition

Cities are among humankind's most complex creations. To do archaeology in a city is to probe into a complicated past that leaves a complicated record. The mere act of excavation is no small challenge, and the analysis of the wealth of data recovered is an even greater one. An entire city may be thought of as an individual site or it may be broken down into a multitude of sites – individual properties that have changed hands, and possibly shape, many times and been used for many different purposes.

Although the archaeology of cities is not new and, in fact, is one of the oldest fields of endeavor – think, for instance, of Rome, Ur, or Teotihuacan where some of the discipline's pioneers concentrated their energies – doing archaeology in younger cities is different and is the focus of this entry.

This kind of urban archaeology is in great part the result of historic preservation laws which require the investigation of places within cities that are slated for redevelopment, places where new construction will destroy remnants of what was there before. This is not always the case though. St. Mary's City, the sixteenth-century capital of Maryland in the United States, is an abandoned city that has been made visible by a long-term archaeological program that, among other things, has revealed its baroque plan, based on the plans that were fashionable in Europe when St. Mary's City was founded (Leone and Hurry 1998: 35). More common in the United States and elsewhere, however, are excavations undertaken ahead of new construction within the constraints of time and money (Fig. 1). These kinds of projects have made all sorts of unexpected discoveries, from the creation of new land to forgotten burial grounds, from the recovery of Staffordshire tea sets in neighborhoods known as slums to alcohol bottles in the homes of teetotalers.

Urban Archaeology in Twenty-First Century Perspective, Fig. 1 Excavation of a block in New York City, once part of the notorious Five Points neighborhood, where the Patrick Moynihan Federal Courthouse now stands

Any urban project begins with the detailed study of maps which graphically show the growth and change in cities over time. In the USA, nineteenth-century fire insurance maps are particularly valuable when planning an urban excavation as they delineate lot boundaries and the configuration of major structures, and even some minor ones, within those boundaries (Fig. 2). To know who lived in those structures, urban archaeologists consult city directories, tax records, census records, and deeds. If they are lucky, there will be other pertinent documents like diaries, legal case records, or even secondary sources that

Rebecca Yamin has retired

Urban Archaeology in Twenty-First Century Perspective, Fig. 2 1853 Perris Insurance Atlas map of the New York City block shown in Fig. 1

involve people who lived on the site at one time or another. Such documents are rare, though, since urban projects are more often than not in places where ordinary people lived and worked, people who did not keep diaries and are not mentioned in history books. Historical research is part and parcel of doing urban archaeology, and building a historical context is essential for both investigating the site and especially for interpreting the finds. Urban archaeologists have also adopted scientific techniques developed in other disciplines to squeeze as much information out of the recovered data as possible. Faunal specialists analyze animal bones to reconstruct diet and butchering patterns, archaeobotanists use microscopic plant remains to reconstruct environmental conditions as well as to provide information on diet and medicine, and palynologists identify pollen relating to historic plant communities. The microscopic eggs found in night-soil deposits are identified by parasitologists to speculate about diseases in historic populations, soil chemistry is sometimes used to define activity areas, and the identification of bugs (entomology) may be used to define environmental features and household products.

Historical Background

Some of the most dramatic finds in cities relate to the manipulation of landforms. Maps show the changing configuration of New York's shoreline beginning in the seventeenth century, but archaeological excavations have also revealed the depths and contents of the fills used to create new land (Cantwell and Wall 2001: Chapter 13). A project in the 1980s at 175 Water Street in Lower Manhattan encountered a 92-foot-long, 25-foot-wide merchant ship that had been used to contain fill at the eastern end of four water lots stretching out into the East River. At another site in Lower Manhattan (the ASSAY site), a series of late eighteenth-century timber wharves that had been filled and built upon in the nineteenth century was uncovered (Fig. 3). Wharves have also been found under made land in Philadelphia, Boston, Baltimore, Albany, and San Francisco in the United States, and in a variety of European cities including London, Dublin, Amsterdam, Dordrecht, Bergen (Norway), and some sites in Denmark (McDonald 2011). Besides the research value of comparing wharf construction and interpreting waterfront activity, these filled structures reveal the premium put on urban land and the effort that went into creating it before machines were available to do the earth moving.

Wharves are not the only made land in cities where land was at a premium. A whole harbor was covered over in Istanbul leaving at least 22 shipwrecks in situ. The site, known as Yenikapi and discovered during construction of a transportation hub in the early twenty-first century, covered an area about the size of ten city blocks and was dug completely by hand, sometimes down to a depth of 25 ft. (Rose and Aydingün 2007). Besides boats, the excavation uncovered a limestone breakwater that protected the city's first harbor, a

Urban Archaeology in Twenty-First Century Perspective, Fig. 3 Timber wharves uncovered on the assay site in Lower Manhattan, New York City

possible length of Constantinople's original wall, the walls of a charnel house later converted to a tannery, and all the things expected in a harbor – anchors, ships' fittings, and hundreds of amphorae. Less common were well-preserved objects made of leather and wood, preserved because of the waterlogged anaerobic conditions. Extraordinary finds were immediately conserved, removed from the field, and placed on display in the Archaeological Museum of Istanbul, an ideal practice rarely possible while an excavation is still underway.

Most modern cities are built on many layers of fill, and figuring out the stratigraphy in the fill (or fills) is a major task of urban archaeology. This is as true in Istanbul as it is in New York. The strata, or layers, may cover evidence of sequential occupations, often alternating between old living surfaces and material used to cover the surfaces and support new ones. As with the filled wharves that supported made land, fill was also used to fill up ponds, abandoned foundations, and backyard features, such as privies, wells, and cisterns. These features frequently served as repositories for all sorts of household and/or workshop trash which becomes the data urban archaeologists use to learn about peoples' daily lives, their work, their tools, their tastes, and their economic wherewithal. Broken dishes, for instance, are mended to define their functions, and matching ones are identified as sets. The decorations on clay pipes are used as clues to group membership (e.g., Masonic order, Irish Fenians), and butchering marks on bones may indicate ethnicity. A basic difference between urban archaeology in the United States and elsewhere is this emphasis on artifacts.

In the USA, artifact assemblages, used as keys to everyday life, provide the major focus of analysis, whereas in England, for instance, it is the organization of space – the way urban places are configured – that receives the most attention. At the Hungate site in York, UK, a broad horizontal approach to excavation was used to expose the complex pattern of foundations present in this nineteenth-century, working-class neighborhood (Fig. 4). Likewise, at the Rocks in Sydney, Australia, cottage foundations were exposed over a large area revealing the tight crowding in that working-class neighborhood. This difference in emphasis probably has more to do with the nature of the sites and cities where they were found than with choice on the part of the investigators. In general, large urban archaeological projects in the USA are in areas where deep nineteenth-century basements destroyed most of the earlier land surfaces and any remnants of structures built upon them. All that is left are the nineteenth-century basement foundations. To find backyard privies, wells, cisterns, and trash pits

Urban Archaeology in Twenty-First Century Perspective, Fig. 4 Densely packed foundations exposed at the Rocks in Sydney, Australia

that predated the nineteenth-century buildings, it is necessary to lift up the basement floors and look beneath them.

There are exceptions though. Remnants of an eighteenth-century African Burial Ground were found in Manhattan beneath nineteen feet of fill (Fig. 5). The land where the burial ground was built originally sloped steeply down to a freshwater pond that was filled at the beginning of the nineteenth century and the land around it was raised and leveled. When buildings were built on top of that land, their foundations did not reach the old ground surface at the bottom of the slope. Over 300 burials were excavated from this surface in the early 1990s, contributing invaluable data on the physical condition of Africans (many enslaved) in eighteenth-century New York and on the origins of the population that had made the Middle Passage (Cantwell and Wall 2001: Chapter 16). Other historic burial grounds have also been excavated on urban sites in the USA including two cemeteries belonging to the First African Baptist Church in Philadelphia, Freedman's Cemetery in Dallas, Texas, Voegtly Cemetery in Pittsburgh, and the UAME Cemetery in Wilmington, Delaware. The covering over of these burial grounds within cities and the reuse of the land are another indication of the premium put on urban land. Rather than treated as sacred space

Urban Archaeology in Twenty-First Century Perspective, Fig. 5 Remains of the African Burial Ground exposed at 19 ft. below grade on a site in Lower Manhattan where the General Services Administration was building an office building

not to be disturbed, they were covered with fill, forgotten, and incorporated into the secular city.

Key Issues/Current Debates

Although the subjects of analysis on urban projects depend to a great degree on the finds, certain subjects recurrently emerge. Class is one of the most important, and urban projects have provided rare access to working-class neighborhoods in several major cities. The Cumberland/Gloucester Street site, investigated in the early 1990s in Sydney, Australia, occupied what had been two half-city blocks where 42 homes had stood. The neighborhood, known as "The Rocks," was cleared in the early twentieth century, but beneath a thick layer of fill, the archaeologists found evidence going back to the earliest occupation of the area. Convict men and women first settled the sloped ground across the harbor from the center of Sydney in the late eighteenth century. Row houses gradually replaced the early terrace ones, and by the middle of the nineteenth century, the neighborhood was regarded by outsiders and historians as "a classic slum" (Karskens 2001: 69). The excavation complicated the picture, producing evidence of refined dining (dinner, breakfast, and tea sets), moralizing china that would have inculcated proper values in children, and wash sets and combs and brushes that indicated an emphasis on cleanliness, all qualities assumed to be lacking in "slum" dwellers (Fig. 6). Even what was left of the houses showed a care for interior decoration and a willingness to spend money on decorative items like china figurines, rugs, and lamps. While there was no question that the inhabitants were workers – many artifacts relating to sewing suggested that women worked as seamstresses and dressmakers – and the neighborhood was overcrowded and unsanitary, it appeared to the investigators that residents' values were not so different than middle-class values of the time. Seen from the outside, the neighborhood looked dangerous, but from the inside – from the archaeological evidence – it looked very different.

The Five Points project in New York City produced much the same result (e.g., Yamin 2001b). Also excavated in the early 1990s, the site was located on a block that was once part of the Five Points neighborhood, known as New York City's most notorious nineteenth-century slum. One side of the project area was inhabited by Eastern European, mostly Jewish, immigrants, and the other by newly arrived Irish immigrants. While the Eastern European residents, many of whom were in the tailoring or used clothing business, may have been economically better off, artifacts recovered from a large cesspool associated with an Irish tenement

Urban Archaeology in Twenty-First Century Perspective, Fig. 6 Moralizing China recovered at the Rocks, Sydney, Australia

indicated that the Irish ate more expensive cuts of meat and owned the same kinds of Staffordshire teawares they would have had at home in Ireland. Their tenement households were overcrowded and households often included borders, but families were more comfortable than they had been in Ireland and did not fit the stereotypes portrayed in the yellow journalism of the day. These two projects in working-class neighborhoods demonstrate the power of urban archaeology to get inside neighborhoods that have previously been portrayed negatively by outsiders through prejudice and fear of "the other."

Another strength of urban archaeology is its ability to bring people close to the past and reveal the connections between past and present. A long-term project in Annapolis, Maryland, invited visitors to view ongoing excavations and talk to the archaeologists who were doing work (Potter 1994). Using critical theory as a framework for interpretation, the archaeologists connected the finds in the ground to the context of the living city. This kind of archaeology has the capacity to demythologize places where excavations are conducted and the people who do them. In Cape Town, South Africa, excavations in District Six, a multiethnic neighborhood that was leveled in the 1970s, revealed the reality of living conditions in yet another neighborhood portrayed as a slum, and the investigators worked with peoples' memories to capture the "complexity, contradictions, and ambiguity" of life in the district (Malan and Van Heyningen 2001: 53). In a different way, the extensive archaeological work done in Quebec City in anticipation of the city's 400th anniversary has made the city's past – its heritage – visible (Moss 2009). Excavations uncovered Jacques Cartier's sixteenth-century fort, the seventeenth-century Chateau Saint Louis including Champlain's house, and the Intendant's Palace which, before it was a palace, was a shipyard and before that, a brewery. Careful attention was paid on this project to botanical and entomological data which revealed changes in the landscape. Recovered artifacts included French-made wares that were being used by Samuel D. Champlain and his retainers as well as assemblages relating to the earliest interactions with native peoples. What is perhaps most extraordinary about the work in Quebec is the support it received from national, provincial, and local agencies, setting an ideal, though probably unreachable, standard for other cities.

While these large excavations done in public view attract a good deal of attention from the press and from visitors, the written reports, weighed down with exhaustive artifact lists and methodological descriptions, have generally been less accessible. A number of urban archaeologists, however, have experimented with using a variety of narrative styles to bring urban data to life (Praetzellis and Praetzellis 1998). In some instances, the narratives serve to clarify the analysis by bringing the many strands of data – artifact, environmental, historical, etc. – together into one interpretation as well as to make the results readable (Yamin 2001a). In the UK, archaeologists working in industrial cities have brought the past in those places to life by paying particularly close attention to context. The interweaving of still standing architectural remnants with archaeological finds is enormously evocative and a powerful way to make sense of cities that have changed so dramatically over time (Belford 2006; Symonds 2006, 2011). This work is yet another example of archaeology revealing a past that is irreparably intertwined with the present.

Urban archaeology is many things. It can be as intimate as the portrait of a lady that begins with her bodkin, the implement she used to lace up her bodice (Beaudry 2011), or as impersonal as the symbolic meaning of changes in orientations of public buildings (Leone and Hurry 1998). Above all, urban archaeology combines data derived from excavation and the analysis of material culture with information drawn from primary documents as well as secondary historical sources to interpret the growth of cities and the experience of urban life.

Urban Dark Earth

Cristiano Nicosia[1] and Yannick Devos[2]
[1]Dipartimento dei Beni Culturali, Universitá di Padova, Padova, Italy
[2]Centre de Recherches en Archéologie et Patrimoine, Université Libre de Bruxelles, Brussels, Belgium

Introduction

Dark Earth is a term used in European urban archaeology to designate thick, dark-colored, homogeneous deposits covering large surfaces generally ascribed to the post-Roman period. Dark Earth constitutes an important part of urban stratigraphy. Taking into account that these deposits

lack any recognizable internal stratigraphy and that they often formed over several centuries, their study requires an adapted research protocol and case-by-case investigation. The systematic study of Dark Earths from an environmental perspective enhances our knowledge of the array of human and natural events that shaped European cities.

Definition

The term Dark Earth does not correspond to a soil classification name (e.g., in soil taxonomy, FAO/WRB, etc.) nor should it imply a univocal archaeological interpretation. The term is used in substitution for other terms present in older literature such as "dark layers," "black layers," "black earth," "made earth," or "dark made earth" (see Macphail et al. 2003; Brogiolo 2011). In Eastern Europe and Scandinavia, the expression "cultural layer" is often used (Krupski et al. 2017). In this chapter the adjective "urban" is employed in order to avoid confusion with "Amazonian Dark Earths." Urban Dark Earth indicates dark-colored, humic, and poorly stratified units, often formed over several centuries, frequently rich in anthropogenic remains (brick, mortar, tile, charcoal, bone, pottery, slag, etc.) occurring over large surfaces in urban contexts. More specifically, urban Dark Earth *stricto* sensu is applied to indicate units situated in between stratified deposits of antique cities (between the first and the third to fifth century CE) and medieval ones (from the eleventh to twelfth century CE onward). More detailed discussions on the definition of "urban Dark Earth" are offered by Macphail et al. (2003), Galinié (2004), Fondrillon (2009), and Devos et al. (2009, 2011).

Historical Background

Interest in urban Dark Earth has developed since the late 1970s as part of the study of the transformations of urban space after the collapse of the Roman Empire in the United Kingdom, Italy, and France (Nicosia et al. 2013). The homogeneous nature of Dark Earth, together with its thickness, has often led scholars to interpret it as the result of a single process, natural or anthropic, to explain its origin. Such interpretations explain urban Dark Earths as alluvial deposits, as simple accumulations of urban dumps, as massive backfill units for ground-rising purposes, as gardens, or as urban horticultural plots. However, the application of analytical methods of geosciences to Dark Earths (especially soil physicochemical analyses and soil micromorphology) has revealed that they result from a complex interplay of many diverse anthropic activities and natural processes. The first examples of the use of these analytical techniques date to the early 1980s at urban sites in the United Kingdom (Macphail 1981). In Italy, a geoarchaeological approach involving the use of soil micromorphology was applied to the study of Dark Earths initially by Cremaschi (1992) in the city of Ferrara. In France, the use of an interdisciplinary protocol for the analysis of Dark Earth involving historians, archaeologists, and geoscientists was advocated in 1995 by Cammas et al. (1995). In Belgium, a pioneering multidisciplinary study was made in the historical center of Ghent in the 1990s (Nicosia et al. 2017).

At the break of the new millennium, an expansion of research on urban Dark Earth can be noticed. This entails a geographical diffusion to Scandinavia and Central and Eastern Europe (see, e.g., Heimdahl 2005), as well as the development of a more solid framework:

- Several research protocols are proposed, involving the integration of different disciplines (e.g., archaeology, geoarchaeology, archaeobotany, archaeozoology, etc.) (see, e.g.: David et al. 2000; Laurent and Fondrillon 2010; Devos et al. 2011).
- A sampling rationale for Dark Earth has been developed (Laurent and Fondrillon 2010; Nicosia et al. 2017).
- Besides the application of traditional archaeological and geoarchaeological approaches, a series of new methods are applied: geophysics (David 2004), macrobotanical studies (Heimdahl 2005), micro-artifact studies and analysis of the coarse content (Sidell 2000), 3D mapping of Dark Earth (Borderie et al.

2014), and phytolith studies on thin sections (Devos et al. 2013).

Key Issues/Current Debates

A key issue in Dark Earth studies concerns the understanding of the formation processes hidden behind the apparent homogeneity of these units. Soil micromorphological, physicochemical, and archaeobotanical analyses have demonstrated that they involve several syn- and post-depositional processes. Accretion derives from the input of a vast range of materials, such as kitchen refuse, hearth rake-out, cereal-processing waste, cess, manure, construction materials (stone, brick, mortar, plaster, tiles, wood, earth-based materials, etc.), industrial and artisanal waste, and backfill. Accretion can also result from flooding (see Figs. 1 and 2) and colluvial and eolian processes. Successive phases of human reworking (plowing, digging, robbing, etc.), bioturbation (rodents, earthworms, enchytraeids, roots), and weathering of earth-based materials and organic remains have been reported to cause the obliteration of any original stratification or sedimentary structure and the ultimate homogenization of Dark Earth. Under the microscope it is possible to observe that charcoal, ceramics, bone, and even coprolites become heavily fragmented and may develop a random and unoriented distribution throughout Dark Earth (Fig. 3). Besides bioturbation, other soil-forming processes are also involved in the genesis of Dark Earth. These correspond mainly to humification of the organic material, decalcification, alkalinization, and oxidoreduction. Part of the sequence can be lost due to erosion by wind and water and/or truncation by successive human activities. Taking into account the complex formation history, several models have been proposed, emphasizing the necessity of investigation of the Dark Earth on a case-by-case basis (see, e.g., Macphail 1994; Heimdahl 2005; Devos et al. 2011) (see Fig. 5).

For historians and archaeologists studying urban history, identifying the palimpsest of activities hidden within Dark Earth and their spatial distribution is of crucial importance. The geoarchaeological approach allows to disentangle such superimpositions. The activities consist, for example, of repeated dumping of waste, cultivation and manuring (see Fig. 4), herding (see Fig. 4), stabling of animals, leather and metal working, decay of insubstantial buildings, and market activities. Several attempts have been undertaken to develop maps showing the distribution of activity zones identified within Dark Earth (Devos et al. 2011; Borderie et al. 2014), thus contributing to understanding the organization of the urban fabric. Dark Earth *stricto* sensu often witnesses the introduction in the post-Roman city of activities typical of the rural world (agriculture, horticulture, herding, soil extraction, etc.). From a historical perspective, they appear in a moment of profound transformation of European cities. Further, according to Galinié (2004) and Brogiolo (2011), Dark Earths *stricto* sensu do not seem to accompany a moment of de-urbanization, abandonment, and impoverishment, but rather a phase in which agricultural activities possibly acquired a particularly important role in the urban economy. It is important to note that, besides natural sedimentary processes, the parent material for Dark Earths *stricto* sensu is primarily provided by anthropic sedimentation, which implies the presence of humans and their activities inside the post-Roman city.

A second issue concerns the chronology of the events during which urban Dark Earth formed. Although micromorphological investigations can often reveal their relative chronology, absolute dating remains an issue. As Dark Earths often formed over several centuries and were subjected to heavy reworking, part of the artifacts and of the datable materials (e.g., charcoal and seeds) were mixed within the deposit, thereby hampering the dating process (see, e.g., the radiocarbon dating of a seventh- to eleventh-century CE Dark Earth sequence from Florence in Nicosia et al. 2012).

A third key topic is the potential of Dark Earth to provide proxies to understand the evolution of the urban environment. As such, the integration of soil micromorphology and the study of phytoliths in thin sections provides a wealth of data on the cultivation of crops within the (pre-)urban area in Brussels and Flanders (see, e.g., Devos et al. 2011).

Urban Dark Earth, Fig. 1 Firenze, Uffizi gallery complex (see Nicosia et al. 2012), an example of Dark Earth in an active alluvial setting. (**a**) The stratigraphic sequence, composed from bottom to top by a construction rubble unit (Unit 120); a layer of clay-loamy alluvium reworked by bioturbation and weathering into Dark Earth; a 40-cm-thick Dark Earth unit deriving from night soiling, domestic waste discard, and episodic input of alluvium (Unit 613); alluvial silty clay loam layer from the Arno river (Unit 611; possibly the large magnitude flood of 1177 CE). Note the sampling strategy: a continuous set of thin sections (rectangles), intercepting both the basal and top interfaces of Dark Earth, accompanied by a continuous series of samples for physicochemical analyses (asterisks), in close association with the undisturbed samples for thin sections. (**b**) Carnivore-omnivore excrement fragment fluorescent under blue light. This type of illumination can be used as an aid to identify organic components in thin section. Additional SEM/EDS analyses highlighted a calcium-phosphate composition, confirming the interpretation as fecal material: 58.1% Ca; 35.8% P; other elements (<3%) Na, Mg, Si, and Al (atom%, without oxygen) (blue light fluorescence, 20×). (**c**) Passage feature deriving from the burrowing action of soil fauna (earthworms, beetles, ants, small rodents, etc.). The occurrence of these features is typical in Dark Earth thin sections and testifies to the strong homogenizing effect of bioturbation. At higher magnifications (100×–400×), many finely comminuted charcoal and charred vegetal particles can be seen within such passage features (plane polarized light, 20×). (**d**) Layered silts and clays filling a pore, as the result of flooding and runoff on the soil surface. This type of features forms at depth in seasonally flooded soils, indicating the periodic input of alluvial material during Dark Earth formation. The alluvium brought in was then reworked by bioturbation and human activities into Dark Earth (crossed polarizers, 20×)

Combined archaeobotanical, archaeozoological, and geoarchaeological studies also permit the reconstruction of local and supralocal landscapes (Devos et al. 2017a).

International Perspectives

The frequent discovery of Dark Earth in towns all over Europe led scholars from different geographic contexts to share ideas and experiences in the analysis and interpretation of Dark Earths with new focus. This resulted in the organization of a series of international meetings. In 2001 a round table on Dark Earth is organized in Louvain-la-Neuve (Belgium) (Verslype and Brulet 2004). During the World Archaeological Conference in Dublin (Ireland) in 2008, a session titled "Geoarchaeology and Dark Earths" treated the European urban and the Amazonian Dark

Urban Dark Earth, Fig. 2 Ferrara, Corso Porta Reno site (see Cremaschi and Nicosia 2010), an example of a fast-accreting urban sequence due to the repeated input of alluvium by the nearby Po river. Dark Earths *stricto* sensu did not form at this site because accretion was too fast for soil-forming processes, especially bioturbation, to completely homogenize the deposit. (**a**) The stratigraphic sequence of the site, with occupation deposits (dark-colored layers), dating to the eighth to thirteenth centuries CE, intercalated to alluvial layers (light-colored layers). (**b**) View in thin section of alluvial fine sands and silts. Note the presence of laminations (plane polarized light, 20×). (**c**) Occupation deposit in thin section: the strong parallel horizontal orientation of the coarser components (mostly charcoal and charred matter) and the massive microstructure are linked to trampling and compaction (plane polarized light, 20×)

Urban Dark Earth, Fig. 3 Brussels, Court of Hoogstraeten site (see Devos et al. 2013). Microphotograph showing the fragmentation of coprolithic material (plain polarized light, 20×)

Earth. Dark Earths were also a key issue during the "Journée d'étude: Géoarchéologie de l'urbain" in Paris in 2009 (Borderie 2011) and the "Conference on the Environmental Archaeology of European Cities in Brussels" (2015) (Devos et al. 2017b). During all these meetings, the problematic of Dark Earth, its definition, and the perspectives for further research were thoroughly discussed. This also resulted in an exponential rise in the amount of publications and communications on the subject involving collaboration of scholars from different countries (e.g., Nicosia et al. 2013, 2017; Borderie et al. 2014) and attempts to standardize research procedures (see, e.g., Nicosia et al. 2017).

The research protocols developed for the study of urban Dark Earth are increasingly used to study the so-called rural Dark Earth: thick, humic,

Urban Dark Earth, Fig. 4 Brussels, rue de Dinant (modified from Devos et al. 2009), an example of Dark Earth formation due to a succession of human activity and natural processes. The lower part witnesses grassland. Evidence is the open microstructure with abundant earthworm granules (biocalcite) (**a**) and a phytolith spectrum typical for grassland (see Devos et al. 2009). The upper part of the Dark Earth results from reworking of the soil and the growing of crop fields. Among the evidence the combined presence of ploughmarks, eggshell (**b**), mortar (**c**), bone (**d**), phytolith markers for cereals (**e**), and enhanced concentrations of phosphorus and bases revealing enhanced chemical fertility (**f**) (see Devos et al. 2009)

Urban Dark Earth, Fig. 5 Simplified model showing the main components, activities, and processes involved in the formation of Dark Earth (Based upon Macphail 1994; Goldberg and Macphail 2006; Devos et al. 2011)

homogeneous, dark-colored layers that are found on rural sites (Goldberg and Macphail 2006).

Future Directions

The lack of internal stratification of urban Dark Earth deposits at the macroscale is particularly problematic for urban archaeologists as it runs contrary to the concept that "one stratigraphic unit equals one action" (Harris 1989). However, many interdisciplinary studies have proven that, in many cases, Dark Earth represents a palimpsest of different activities and natural processes subjected to thorough homogenization and to weathering (Fig. 5). The resulting ostensible homogeneity of a deposit belies its complexity. Although soil micromorphology has proven a powerful tool in elucidating the use of space and the cultural activities associated with Dark Earth formation, further integration of other analytical methods is advocated. Specifically, thin section study can be integrated with soil physicochemical analyses, instrumental analyses (e.g., electron microprobe, SEM/EDS), phytolith and parasite analysis, micro-archaeology, and spatial analysis of artifact distribution.

Future study should include research on the origin and evolution of the organic matter in Dark Earth, especially of pyrogenic organic matter, and the collaboration between soil micromorphologists and pedo-anthracologists.

Taking into account the complexity of Dark Earth, its study requires a systematic analytical approach. Beginning with appropriate research questions, this includes quality sampling, knowledge of natural processes acting in specific contexts, and the application of solid interpretive models drawn from archaeological excavations.

Systematic recording and study of all Dark Earth within towns should not only improve our knowledge on the spatial organization of the different neighborhoods and their evolution but will also contribute to our understanding of the evolution of the urban landscape and its vegetation.

One final caveat must be issued regarding the expression "Dark Earth." As mentioned above, the term does not indicate a specific soil type according to one of the systems of soil classification. Archaeological features (burials, walls, hearths, etc.) often appear to "float" in these deposits, and it is often very difficult to identify negative features during excavation. Also, Dark Earths are encountered in

both urban and rural contexts and not necessarily where a previous Roman-age occupation exists. The term "Dark Earth" is useful for identifying these diverse deposits on account of their common features but should be employed as archaeological jargon instead of scientific soil classification. Indeed, as its presence in the *Encyclopedia of Global Archaeology* suggests, the term has been well established in archaeological literature for many decades. This chapter has attempted to emphasize the importance and commonalities of urban Dark Earths while at the same time demonstrating that characterizations and interpretations of Dark Earth must be made on the basis of context. Moreover, only through multi- and interdisciplinary approaches like those described here will further light be shed on the centuries of history "hiding" in the dark of Dark Earth.

Urban Heritage

Anna Karlström
University of Queensland, Aboriginal and Torrest Strait Islander Studies Unit, Brisbane, QLD, Australia

Introduction

As a concept, urban heritage is global and has a worldwide scope, but at the same time it harbors a number of notions and must be seen in relation to the different and specific contexts with which it deals. Urban heritage issues engage not only heritage managers and archaeologists but also geographers, landscape and urban planners, engineers, architects, anthropologists, and historians, among others. As cultural heritage issues in general, those concerning the urban heritage are interdisciplinary and multifaceted. The urban heritage often has a position "in between." On one hand, it is constantly changing and under the threat of being destroyed due to the nature of urban development, and on the other hand, it is protected and conserved because of its historical values. Heritage structures are often regarded as a passive setting to the broader scope of the growing modern city. The ultimate goal is to strive for integration so that historic qualities and modern urban conditions can develop side by side.

Definition

Commonly, urban heritage is defined as the layers of historical, physical remains that constitute contemporary urban areas, that is, the built heritage with architectural and historical value or the "monuments" of a city (churches and other religious buildings, castles, city walls, palaces, and institutional buildings). In addition to this, urban heritage includes the urban plan (sites, streets, plots, and block plans of the buildings) and building and land utilization. However, the research complex of cultural heritage in the context of contemporary urban development operates with an expanded concept of heritage, not only including the physical remains and historic preservation and urban development policies, but also considering the political and sociological constitution of the city in regard to its capacity for social integration and local democracy. Urban heritage is both tangible and intangible, that is, including people that live in and are connected with urban areas and places, customs, and beliefs that are of less tangible character but important for the articulation of space and the built environment.

Legislation

Urban heritage is managed differently in different countries and depends ultimately on national legislation. Yet, international key organizations that are dealing with general heritage issues are of considerable importance to urban heritage planning and to how urban heritage is defined and managed on international as well as national, regional, and local levels. Various of UNESCO's charters, for example, concern urban heritage issues. From being focused on the protection and conservation of built heritage in urban areas, more recent conferences, papers, and adopted charters about cultural diversity and intangible heritage have expanded UNESCO's scope to reflect on the involvement of local communities. Other organizations influential for the definition and managing of urban heritage are ICOMOS (International Council on Monuments and Sites) and ICCROM (International Centre for the Study of the Preservation and Restoration of Cultural Property). Their conferences, papers, and charters have also moved from being focused on how to protect physical remains toward social aspects of and holistic approaches to urban heritage. In addition to international organizations, there are non-governmental groups, groups representing developer interests, and research groups that support urban heritage management and protection, such as National Trust, historical associations, local action groups, and universities.

The scale and the scope of urban heritage management and protection vary from World Heritage Cities that ascribe to universal values embraced by existing legislation, through National Heritage Areas and Conservation Areas (entire districts or towns) and individual Listed Buildings that ascribe to more specific and local values but also embraced by existing legislation, to Urban Heritage Parks with specific and local values but no official status.

Historical Background

Most likely, people in the urban centers that existed around the world thousands of years ago were involved in different kinds of management of their milieu, although never defined as urban heritage protection.

The earliest concerted efforts to protect urban heritage, as a response to the processes of industrialization and urbanization that were part of the wider modernization process, started in the eighteenth and nineteenth centuries (see Jokilehto 1999, for an overview of the history of European urban conservation). Focus was exclusively on the protection of monuments and grand architecture, albeit with various approaches, as, for example, "aesthetic restoration" aiming at stylistic unity as an illustration of the ideal, followed by the "antirestoration movement" that wanted (inspired by Romanticism) to preserve the remains even if damaged, and modern conservation that recommended "careful restoration." Another approach was to focus on the building's "historicity," that is, to recognize the different layers of the building.

In the 1960s and 1970s, the approach shifted from individual buildings and their conservation toward a wider interest in areas, streetscapes, and environments and from monuments toward vernacular buildings. By the 1980s and 1990s, aesthetic values had been expanded to include social values, and the "spirit of place" was recognized as being important and valuable to the general community and to local groups within these places. The tendency within urban heritage management pointed toward a holistic approach.

Today, urban heritage and urban areas are being transformed by globalization, industrialization or deindustrialization, by growth of tourism industries, and through developments of national and postcolonial identities and population growth, and the holistic approach is now de facto on the agenda, although not always prioritized.

Current Debates

As a consequence of this contemporary complex situation, the challenges within the urban heritage field have increased. Ongoing debates evoked by these challenges can be divided into the following themes.

Legislation

The main critique against existing legislation is that laws and international guidelines and policies promoting sustainable urban heritage conservation and development have very little influence in contexts outside the Western world (Birabi 2007: 39). The reason is that these laws, guidelines, and policies, rooted in Europe and directed toward and applicable primarily to situations in the Western world, are not adapted to *non-Western contexts* and are therefore to a large extent neglected in these areas (Zetter and Watson 2006).

Conservation Versus Change and Tangible Versus Intangible Urban Heritage

Another challenging issue concerns UNESCO's World Heritage Cities or Urban World Heritage Sites. There are obvious difficulties of translating traditional conservation concepts, centered around *authenticity* and *preservation*, to the multifaceted and changing contexts urban World Heritage Sites represent (Pendlebury et al. 2009: 349). The result is that the urban experience is ignored and that we get urbanity without urbanness. This debate does not only concern urban World Heritage Sites but rather urban areas and urban heritage in general (Nasser 2003: 467). It is also connected to the debate on tangible and intangible heritage. Even though existing approaches to urban heritage aim at being holistic and have grown wider to embrace both tangible and intangible aspects, there are obvious difficulties to include the intangible, because the basis within urban heritage management is still to protect and to preserve (Tweed and Sutherland 2007: 62), which contradicts the nature of the intangible.

Global and Local

The concept of globalization is a phenomenon with long history, even though the terminology is modern. Its definitions are manifold, depending on the context, but in general we speak about the removal of barriers between (national) borders. Within cultural globalization, this results in a homogenization of culture. Common assumptions about cities throughout the world are that they are essentially homogeneous in both form and definition, that they are based on Western models, and that they are a result of globalization – furthermore, that economic globalization inevitably leads to cultural globalization and that this is connected to the emergence of the urban "explosion," which started with the economic boom in the 1960s and is still proceeding rapidly. These developments result in a growth of a homogeneous "urbanness" and a loss of national and local characteristics and distinctiveness. In this view, globalization presents a major threat to the maintenance of the cultural heritage of urban areas. A reaction against this perspective, evolving from the idea that the situation is more complex, has resulted in the common view that economic globalization instead leads to cultural localism, with increased local resistance to cultural globalization, resulting in an even stronger protection of the local cultural identity as an essential component of sustainable urban development. In other words, globalization and localization occur side by side, and the balance between

these forces is ultimately what urbanism is about (Karlström 2010: 554; Logan 2002: xii). The complex connections between the global and the local processes can also be seen as a resource for local economic and social development within the urban heritage tourism field (Green 2001: 191). The global and local must not be regarded as dichotomies but rather as inextricably bound together and acknowledged as a powerful resource harboring and offering something of its own, something uniquely urban.

Urbanism and Identity

In close connection to the debates about urban heritage and globalization/localization are debates concerning urban heritage and identity. The core question is whether there is a particular urban identity that is created in the intersection of and in the space between the global and the local, and what characterizes this identity, or identities. Parts of the debate also concern the challenge of identifying and maintaining these identities, of including them as an important and necessary part of the urban heritage (Evans et al. 2011), and of looking at the relationships between how the urban area is seen, its identities, and how it wants to be seen. Much of the input to these debates draws on involvements in community work and research in the politics of urban space and contemporary urban sociology. Through a better understanding of the multicultural and ethnic heritage places in urban areas, they can be used as a tool to promote stability and sustainability rather than seeing them as separated enclaves (Lin 2011). The dynamics of cultural diversity, differentiation, and fragmentation must be seen as positive forces counterbalancing homogenization and integration.

Future Directions

Regardless of whether urbanism is a result of, or results in, globalization and localization, and whether the study of urbanism involves individual and specific perspectives and/or collective and universal perspectives, it forces us who deal with past and present urban heritage to consider this new set of multi-scalar engagements. Debates concerning globalization within the urban heritage field have recently paved the way for debates about urban heritage in relation to cosmopolitanism. Globalization is seen as something happening out there, whereas cosmopolitanism happens from within. Cosmopolitanism, which has an overarching framework of global politics but also very specific concerns about the individual and the community, "is not a circle created by culture diffused from a centre, but instead [. . .] centres are everywhere and circumferences nowhere" (Meskell 2009: 5). This and the fact that the majority of the world's population now lives in cities result in that urban areas and urban heritage become a source of both growing cultural conflicts and growing cultural dialogues (Keith 2005). These new forms of cultural hybridity need to be acknowledged and further debated. With the growing pressure from the outside on urban areas and on the urban heritage, questions about sustainable development and urban heritage tourism are also highly important to develop further.

Urban Landscapes: Environmental Archaeology

Allan Hall[1], Harry Kenward[1], Mélanie Rousseau[2] and Allison Bain[2]

Introduction

Archaeological deposits formed within settlements large, long lasting, and complex enough to be called towns pose interesting challenges for the environmental archaeologist. They are places where large concentrations of organic materials are always likely to have been amassed, used, and discarded. Consequently, in some cases organics – including delicate plant and animal fossils – form a large part of the archaeological record, as in the early medieval towns of Northern and Northwestern Europe (e.g., Carver's (2009: 11) "organic crescent"). By contrast, many urban deposits, particularly if they are well-drained sedimentary contexts, are almost devoid of the remains of animals and plants other than the most decay-resistant charred plant material, bone, and shell. Stratigraphy may be very complicated, however, with repeated reworking of deposits over time.

Definition

Urban dwellers live under conditions very different from those in the surrounding countryside, but nevertheless the town has a landscape of a sort, created primarily by human activity. The substratum was largely the detritus of former occupation, but it supported a mosaic of habitats for plants and animals. This patchy environment was what the human occupants experienced, and it varied greatly with geography and time. This landscape can be considered at scales from that exploited by a minute insect right through to the various zones into which towns inevitably became divided socially and functionally.

Key Issues/Current Debates/Future Directions/Examples

For those times and places where there is a record, the historical approach to past urban landscapes is often extremely evocative (Cockayne 2007). However, the sources for such accounts must inevitably be biased towards the outrageous, emphasizing behavior and environments which by the general standards of the time were considered unacceptable and even requiring civil action. Comments that towns were clean do exist, but

are very rare! Archaeology provides a way of reconstructing past environments, living conditions, and human activities where there is no documentation and of countering the bias of documents.

Remains of almost any organism which found its way into the town may be preserved under one set of circumstances or another. The range of surviving evidence reflects what went into the ground, modified by inground preservation during the life of the deposits, including any recent decay. For the purposes of discussion, potential biological remains can usefully be divided into labile (those organisms or tissues which almost inevitably decay very rapidly and are rarely encountered), delicate (those which require special conditions, such as anoxic waterlogging, dehydration, charring, mineral replacement, or the presence of toxic mineral salts), and robust (those, such as bone and shell and also of course charred or mineral-replaced material, which survive in a wide range of deposit types). Some deposits contain almost all kinds of material, presenting what is almost an embarrassment of riches. At the other extreme, an acidic well-aerated deposit may preserve almost nothing, even bone and shell having dissolved. Taking urban archaeological deposits as a whole in time and space, the majority have limited preservation, yielding robust materials (mostly bone), charred plant remains, and (less often) mineral-replaced fossils. Such remains are usually primarily of value in economic reconstruction and give rather little indication of urban landscapes beyond perhaps certain local craft activities.

What is the nature of the "environmental" evidence? Firstly, there is the sedimentary matrix in which fossils are preserved, itself often composed of both organic and inorganic material. The deposits formed in towns are almost always *not* soils in the sense of surface-forming, biologically stratified, and long-lived systems (so that to call them "soils" is a misnomer; "sediments" is more correct). Nevertheless, many of the techniques of soil science can be applied to elucidating the environments in which deposits formed (e.g., Davidson et al. 2006). Studies of the very fine organics have barely started, but available techniques include various investigations of biomolecules, such as coprosterols and DNA (e.g., King et al. 2009; Bull and Evershed 2012).

Most attempts to reconstruct the environments of ancient towns have been based on the recognizable remains of organisms. These may be microscopic, with pollen perhaps the most familiar, but also phytoliths, diatoms, fungal spores, eggs of intestinal parasites, and rarely even diatoms. At the other extreme are the sorts of large remains which are obvious during the excavation process – larger bones and shells, timbers, nutshell, and fruitstones. In between these lie what are conventionally called "macrofossils" (though they generally require a microscope for analysis): most remains of plants and macro-fungi, the exoskeletons of crustaceans, insects and other arthropods, the smaller molluscs, and small bones. Not all of these have received the attention they deserve; fungal spores and mites have been particularly neglected but probably have considerable potential, the latter for detecting livestock in towns (Schelvis 1994) – the bones of domestic animals obviously cannot be used as evidence that they were *kept* in urban areas, but evidence for large quantities of their dung is usually more convincing. Remains of small vertebrates, on the other hand, may contribute substantially to painting a picture of the urban environment (Boucher 2000; O'Connor 2000).

What is *recovered* from the buried resource depends on the archaeological strategy (the sampling program) and support for post-excavation work, which may be largely a function of political expediency. Research excavations inevitably produce more information about single locations, but the sort of brief assessment preceding development which is *de rigueur* through many areas of the world can be argued to produce a broader picture (Hall and Kenward 2006).

The reconstruction of the past urban environment depends on numerous "point" reconstructions. Towns are (and were) far too heterogeneous for one or a few "sites" to be representative of urban complexity. Unfortunately, almost no towns have been studied to the extent that this complexity can be reconstructed to produce a picture of urban zonation for any period,

let alone for their whole history. Even York and London, probably the towns most intensively and extensively studied by environmental archaeologists, have not reached this point. There is certainly considerable potential, however, as shown by some work on insects (Kenward and Carrott 2006), a synthesis of biological evidence from Viking-Age York, England (Hall and Kenward 2004), and studies spanning the Iron Age through to the medieval periods in Novgorod, Russia, and Uppsala, Sweden (Hellqvist 1999).

We can look at the landscape of a town from a number of aspects, notably the evidence for seminatural environments, for the appearance of streets and yards (as perceived by all the senses), for accumulations of waste, for the presence of open water and its quality, for the nature of buildings (a major determinant of the appearance of towns), for urban "wildlife" (including pests, parasites, and commensals), and for the various activities of the occupants both in and outside of the built environment.

In some cases, we can surmise – on the basis of evidence from plants and insects – that areas were invaded by vegetation and probably took on a seminatural appearance, much like a modern urban wasteland area. In others, the same kind of evidence, as well as the nature of the deposits themselves, points to extremely intensive disturbance, to the extent that only a few hardy weeds were able to establish a roothold (Hall and Kenward 2004). Not surprisingly, in view of this, evidence for urban trees is vanishingly small in older periods, while pollen analyses have provided details on nineteenth century backyards in Lowell, Massachusetts, USA (Kelso 1993). In many cases, where there is preservation of delicate remains in deposits formed on external surfaces (usually in yards), the insect remains suggest for European sites fairly unclean conditions, not at all enhanced by the abundant open cesspits present in many cases.

On the other hand, multiple environmental techniques applied on various urban sites in the region around Boston (USA), probably the most studied urban landscape in North America (e.g., Mrozowski 2006), indicate a different type of yard landscape. These studies suggest that early residential backyards were also mainly composed of disturbed sediment but that these were dry and included gardens of exotic and edible as well as weedy plants. However, with the growth of cities, household gardens tend to disappear from yards.

The visual appearance of structures is fundamental to the urban landscape. While excavation evidence is generally, and quite rightly, seen as the primary source of information concerning the nature of buildings, biological remains have the potential to contribute detail. Many buildings were entirely "biological" in that they were constructed of organic materials: timbers, small wood, plant thatch, stripped bark, and moss for packing crevices. Obviously, archaeobotanical analysis is required to identify such materials before it is reasonable to reconstruct buildings conceptually above the foundations revealed by excavation. The greatest unknown in most such cases is the nature of roofing, for which there is surprisingly little bioarchaeological evidence (however, see Letts et al. 2000).

The insides of buildings were as much part of the urban landscape to the occupants as were outdoor areas. Substantial progress has been made in reconstructing indoor environments at some sites, notably in Europe in the Viking Age/early medieval period. The most substantial study of living floors was that for Anglo-Scandinavian Coppergate, York, where deposits undoubtedly formed during occupation attested to substantial accumulation of filth and to conditions (probably below the surface) moist enough for the invasion of insects more often found in waterside litter (Fig. 1). There was also abundant evidence for drier conditions, presumably both in the surface levels on which people stood and in the structure of the buildings (Kenward and Hall 1995). At Coppergate, there was a contrast between floors which seem to have been domestic and those which were more probably workshops. This kind of differentiation can sometimes be seen elsewhere, for example, at the eleventh-century workshop at Viborg, Denmark (Iversen et al. 2005).

Interpretation of the very "mixed" assemblages of biological remains found in urban deposits can be, to say the least, challenging (Figs. 2 and 3).

Urban Landscapes: Environmental Archaeology, Fig. 1 A twelfth-century cesspit at 16–22 Coppergate, York, complete with seat, during excavation; the fills of pits like this may be rich in evidence for food waste (Figs. 2 and 3) and the remains of parasites (Fig. 3). (Photograph: York Archaeological Trust)

Urban Landscapes: Environmental Archaeology, Fig. 2 Concretion of human fecal material of the kind typically found in pits like that shown in Fig. 1; the fruitstone embedded in the concretion is from a blackthorn fruit (sloe, *Prunus spinosa* L.), a well-collected species

Two approaches to disentangling such complex mixtures have been taken: the use of species association analysis (Carrott and Kenward 2001; Smith 2012) and identification of activities and materials through "indicator groups" and "packages" (Kenward and Hall 1997; Hall and Kenward 2003). The application of species association analysis to Roman sites in Carlisle, NW England, has given pointers to contrasting conditions across the town (Kenward and Carrott 2006). Indicator groups – based on as wide a range of biological remains as possible – lead us to better understanding of the kinds of materials and activities in particular areas of towns, with obvious implications for local environments. If we establish that slaughtering, skin cleaning, tanning (for skins), or retting or dyeing (for textile manufacture) took place, for example, it is very likely that the locality was blighted by accumulations of foul matter, bad smells, and polluted water (Fig. 4).

Researchers in bioarchaeology tend to emphasize those periods with good organic preservation (itself probably primarily the results of large-scale accumulation of organic matter incidental to human activity) when discussing conditions in past towns (Fig. 5). Thus, in Northwest Europe the emphasis is on the earlier Roman period of Britain and on the Viking Age to the end of the medieval period. Preservation in surface-lain deposits is rare in Roman stone-built towns and becomes less common in deposits formed in the later in the medieval and into the postmedieval periods. On North American urban sites, studies tend to focus on specific contexts offering better chances of preservation. Within settlements, there is a clear bias towards the less salubrious areas, where organic matter accumulated and self-preserved, with preservation in the more affluent areas often restricted to deep cuts (cesspits,

Urban Landscapes: Environmental Archaeology, Fig. 3 An example of extremely delicate plant material preserved in waterlogged urban deposits – leaf epidermis of leek, *Allium porrum* L. Also present (in one of the marginal teeth of the leaf fragment) is an egg of the intestinal parasitic worm, *Trichuris*, probably *T. trichiura* (Linnaeus)

Urban Landscapes: Environmental Archaeology, Fig. 4 An elytron of the heathland weevil *Micrelus ericae* (Gyll.). Found in tenth-century deposits in the center of York, it is part of a group of organisms representing imported material (heather and/or turves from heathland)

Urban Landscapes: Environmental Archaeology, Fig. 5 Taking a sample column for environmental analyses at the Intendant's Palace Site (CeEt-30) in Quebec City, Canada. (Photograph courtesy of Université Laval)

latrines, and wells). Though biased, these areas may provide interesting information on the evolving urban landscape, for example, in privies in Colonial Boston (Bain 1998; Bain and King 2011).

Thus, preservation determines the richness of the information we can recover from biological remains, with the greatest amount of evidence in what are conventionally called "anoxic waterlogged" deposits (Kenward and Hall 2004), but this resource seems to be threatened by recent inground decay. Fortunately, in many periods and places, the abundance of documentary evidence for environments is inversely proportional to that from the ground.

Urban Planning in the Greek World

William Aylward
University of Wisconsin-Madison, Madison, WI, USA

Introduction

Urbanism is one characteristic that binds the ancient cities of Greece to earlier developments in Mesopotamia and the Near East. Cities in east and west shared a number of features in common, including an urban center, a tutelary deity worshipped at a central sanctuary, and dependence on a rural hinterland for sustenance. But monarchs ruled in the east, and Greek cities evolved along a different, complex, and varied path, experimenting with new social and political institutions and an ideology of citizenship. It is therefore remarkable that urbanism first emerges in ancient Greece at the end of the sixth century BCE, at the very same time when increasing contact with the Persian Empire becomes a catalyst for experiments with empire in Greece (Morris 2006: 26–51).

Ancient Greeks were first and foremost agriculturalists; so urbanism, when it appeared, was made possible by stable environmental conditions and an abundant and diverse supply of food, such as grain, olives, grapes, and fish. Geography was also of consequence. The earliest Greek cities were located on or near the coast, and this reflects the importance of maritime trade as a factor for urbanism. The sea also provided natural defenses for civilization to grow and develop with protection from the outside. Peculiar to ancient Greece, the many isolated valleys that formed natural barriers between cities encouraged attitudes about control of resources that ultimately enabled urbanism.

Definition

Urbanism, a state of existence, is quite distinct from the process of urbanization, state formation, and questions about the emergence of civilization. Ancient Greek cities are distinguished by settlement size, density and structure, as well as by topographical organization, occupational pattern, and architecture as an expression of power, identity, and culture. But which of these factors are markers of urbanism? Urbanism is not merely about the size of a city or its population. Nor is the relationship between nucleated settlements and urbanism interdependent: A nucleated settlement was not a prerequisite for an urban center. Urbanism in ancient Greece is found where one also finds mobility, surplus wealth, domination, consumption and exchange of resources and territory, and an administration to manage it all. Any definition more specific would limit the varied and complex nature of the literary and archaeological evidence for ancient Greek cities.

It is also important to distinguish between urbanism as it relates to the physical appearance of cities and the phenomenon of the rise of the polis, or city-state, whose emergence and growth at a remarkable pace in Greece in the eighth century BCE. was accompanied by substantial social and political transformations. As it turns out, urbanism and polis ideology were different, since urbanism required mobility of people and goods beyond a city, and a polis required belonging and obligation to the idea of a community (Whitley 2001: 165–168). Thus, an accurate definition of urbanism for any city must take into account degrees of interaction with the territory and resources around it. This is of some consequence for orthogonal town-plans as a factor for urbanism, especially because by design, they reveal interest in the Greek principle of *isonomia*, which nurtured belonging by granting all citizens equal access to resources.

Political independence appears to have been a prerequisite for urbanism in ancient Greece, but a complete definition of urbanism involves much more than the ideology of independence and citizenship. In ancient Greek cities, only in politically independent units does one find diverse functionality of urban space for politics, religion, commerce, and entertainment. Such activities played out in the standard suite of public buildings for a Greek city, including sacred architecture, the theater, prytaneion, bouleuterion, and gymnasium, among others. Beyond the city center, extramural sanctuaries enforced a city's claims to territorial control. One challenge to using population size as a factor for urbanism is illuminated by demes in Attica, where one does not find such facilities for diverse function of urban space in demes politically dependent on Athens, even though some of them had populations that exceeded politically independent cities elsewhere in Greece.

At a level somewhat harder to measure, urbanism also concerns the character and personality of a city and its cultural sophistication. Here one must also consider the challenge of escaping the corruption of our perspective by Medieval and early modern urbanism.

Historical Background

Homer and Hesiod, our best sources for early Greek society down to the seventh century BCE in Greece, convey little, if anything at all, about urbanism. Archaeological evidence shows that, in the eighth and seventh centuries BCE, discreet villages coalesced into larger communities for political and economic reasons, especially in southern Greece. Some cities may have had as many as 10,000 inhabitants. Still, few today would argue with the conclusion that "whatever factors made possible the achievement of Archaic Greece, an advanced urban culture was not one of them" (Snodgrass 1981: 157–158). But even in this period, one can perceive a harbinger of forces for urbanism developing in sanctuaries, which dominated city centers, enforced territorial claims on the periphery of communities, encouraged mobility, and were adorned with sacred architecture increasing in monumentality.

It is not until the eve of the Classical period in the late sixth century BCE. when increased diversification of the function of space in a very small number of cities, like Athens and Syracuse, allows for discussion of urbanism. From this point on, urbanism was propelled forward by the rise of imperial administrative centers whose populations estimated at 40,000 exacted wealth and resources from territories far beyond their immediate hinterland (Morris 2006: 27, 36–46). In the fourth century BCE., these trends were imported to Macedonia, whence aspects of Greek urbanism were spread to Egypt and the Near East by the campaigns of Alexander the Great. Here and in the ensuing Hellenistic period, urbanism was concentrated in fewer, larger cities by monarchs who employed synoecism to control subjects and resources. In Asia Minor, especially, the impact of Hellenistic urbanism on Roman cities is clear (Parrish 2001).

Key Issues/Current Debates

Indicators of Urbanism

Were ancient Greek cities "urban"? This enduring question about ancient Greek urbanism is rooted in debate about indicators for it. Osborne and Morris revived discussion over 30 years ago,

reacting to M.I. Finley's use of categories devised by Max Weber in 1921. For Finley (1977: 325), "The Graeco-Roman world was more urbanized than any other society before the modern era". On the other hand, Osborne (1987: 194), echoing Snodgrass quoted above, has claimed, "urbanization was unknown in Greece." Morris (2006: 27–32, 1991: 37–38) allows that urbanism does not define cities in Greece prior to the late sixth century BCE, but makes a compelling case for the emergence of urbanism with the rise of imperial administrative centers like Athens and Syracuse shortly after 500 BCE. Instances of such opposing interpretations can usually be traced to sources open to multiple interpretation, and the question of ancient Greek urbanism presents no exception. Still, scholarship over the past three and a half decades has landed on a handful of reasonable indicators for urbanism in ancient Greece and excluded an equal number of others.

Substantial discussion has been devoted to the idea that a city was shaped by its countryside, and that urbanism only occurred when a city grew beyond dependence on its hinterland (Osborne 1987: 16, 194–195). A city's ability to grow beyond the carrying capacity of its hinterland was a mark of urbanism brought on by imperial expansion and control, which, in the formula proposed by Morris, did not emerge in Greece until after contact with the Persian Empire (2006: 27–32). According to this argument, indicators for urbanism include the evolution of a city beyond the needs of its hinterland for sustenance and an administration of imperial magnitude. The imperial ambitions of Athens were behind the best, and perhaps singular, example of forces for urbanism in the fifth century BCE. With the exception of Syracuse, they are not reflected in other Greek cities, which did not develop beyond means their countryside allowed them. Such interdependent movement of people and resources between cities makes a case for mobility as a reasonable indicator of urbanism, to the degree that mobility can be distinguished from forces at work in imperial administrations and exchange between city and country (Whitley 2001: 167).

Writing can be another important indicator of urbanism (Sweet 1997: 35–49). Writing transformed communities into urban centers because of its impact on social organization. City administrations, especially those dependent on agriculture, needed a way to keep track of things. Writing allowed for recording and organizing information, managing complex relationships between resources and labor, and controlling a community's mobility and security. All of these are ingredients in the recipe for urbanism. But if, with a few exceptions among prehistoric cities of the Near East, writing and urbanism appear at the same time across the ancient world, what are we to make of Archaic Greece, where writing appears in the eighth century BCE., long before the first cases of urbanism? For Greece in the eighth century BCE., the earliest writing served poetry for a seafaring aristocracy in the unique physical landscape and transformative social and political conditions described above (Powell 2007: 45–53, 59–64). Only about two centuries after its invention in Greece does writing become linked to the economic interests of Greek cities and take on value as an indicator of urbanism.

Other components of ancient Greek cities are harder to justify as indicators of urbanism. Substantial discussion has been devoted to trade in specialized crafts, especially pottery, as an indicator of urbanism. When centers of craft production engage in interdependent trade networks, they begin to resemble forces in a market economy. But the scale of this industrial enterprise was probably never sufficient enough to encourage urbanism in cities (Morris 1991: 38–40; Whitley 2001: 174–179). Town-planning is certainly a component of urbanism, but not a requirement for it. Population size seems to be more a consequence of urbanism than an explanation for it. Nor are walls for city defenses indicators of urbanism for ancient Greece, for not only do they appear around settlements of different sizes in most periods of Greek antiquity, they also tend to appear long after the emergence of politically independent cities (Snodgrass 1981: 157–158, 2006: 274–276; Whitley 2001: 313). In addition to the above, Morris (1991: 38–40) also excludes the presence of an agora as a meaningful index for urbanism in an ancient Greek city. Nonetheless, worthy of mention as a hallmark of the Greek

agora is the stoa, a long, narrow rectangular building with a roof spanning a rear wall and a colonnade on the façade. Its original function was to aid the operation of sanctuaries, where it provided for storage and lodging at these important markers of territorial control. But it was borrowed for civic architecture in classical times, most notably to flank the agora, where it provided civic space for law courts, commerce, and ad hoc political meetings. The functional evolution of the stoa mirrors the social and political transformations that accompanied the rise of urbanism in Greek cities.

Hippodamus of Miletus

If town-planning per se is not an indicator of urbanism, then this raises questions about the impact on urbanism of Hippodamus of Miletus (498–408 BCE), the architect, urban planner, and namesake of the Hippodamian city plan. First off, city plans of Smyrna in Ionia and Greek colonial foundations in south Italy and Sicily like Megara Hyblaia, which all belong to the seventh century BCE, show that Hippodamus theorized and perhaps refined the orthogonal city plan rather than create it. Such plans had broad, straight streets with neat intersections at right angles and an open area in the center of the city reserved for public and sacred architecture in the service of community, spectacle, commerce, politics, and cultural identity. Much of Hippodamus's fame is due to Aristotle's criticism of his ideas, which have not been directly linked to cities with types of plans attributed to him (Wycherley 1962: 17–18; Owens 1991: 4–6; Cahill 2002: 3–5). Aristotle (*Politics* 2.8) called him the inventor of the art of planning cities, whose ideal city had 10,000 citizens divided into three classes (artisans, farmers, and soldiers), with loosely corresponding divisions of land: sacred, for worship of the gods, public, to support the soldiers, and private, as property for the farmers. Aristotle called this system impossible and confused, and the actual impact of Hippodamus on Greek city planning must be examined within the context of the polemic in which it is conveyed.

Hippodamian style cities of the Classical period are not hard to find (Owens 1991: 51–73; Hoepfner and Schwandner 1994: 17–67). The only city plan Aristotle attributed to Hippodamus was the Peiraeus, laid out sometime after 478 BCE, with an agora named for its planner (Gill 2006: 1–15). Estimated to have a population of about 25,000, archaeological evidence has revealed an orthogonal plan complete with insulae (city blocks) and courtyard houses of the prostas type also found at Priene a century later (Hoepfner and Schwandner 1994: 22–50).

Without naming the planner, Strabo (14.2.9) implies that Hippodamus laid out the city of Rhodes in 408/7 BCE. There is little agreement about ambiguous evidence for Hippodamus's involvement in city planning at his home town of Miletus in c. 479 BCE and at the Athenian panhellenic foundation of Thurii in southern Italy in 443 BCE (Burns 1976: 414–428; Cahill 2002: 301–302 note 6; Gill 2006: 1–15).

The career and impact of Hippodamus on urbanism are both elusive (Whitley 2001: 315–319). City plans on orthogonal principles predating the career of Hippodamus are found in pre-classical cities like Megara Hyblaia on Sicily, Vroulia on Rhodes, and Marzabotto in Etruria. Cities not attributed to Hippodamus or his influence, but which were laid out with perpendicular streets and regular city blocks, are also known from many other sites in Greece and Asia Minor from the Classical and Hellenistic periods, such as Abdera, Halicarnassus, Ilion, Olynthus, Pergamon, and Priene (Hoepfner and Schwandner 1994; Parrish 2001). It turns out that Hippodamian plans have less to do with a single moment of invention and more to do with circumstances in which Greek cities were formed. Cities that grew out of long established villages, like Athens, were unlikely to have orthogonal plans, whereas new foundations, like the Peiraeus, were more likely to have regular orthogonal plans.

Future Directions

Future study of ancient Greek urbanism is tied to new discoveries in archaeology, especially those with potential to inform on the indices for urbanism described above. At the same time, a substantial challenge to archaeologists and readers of

their work, and one far too often neglected by studies that appeal to town plans, is the reproduction of restored plans and conceptual reconstruction drawings by artists. These provide false impressions of completeness and consistently neglect to compare what has been found to what might still lie beneath the surface. Beyond archaeology, research questions will also continue to evolve in new directions. A case in point is a recent Social Darwinist theoretical exercise which, despite controversy over the extent to which genes control behavior, aims to link ancient Greek urbanism to the success of eusocial communities by transplanting genetic models for insect communities to human societies (Bintliff 2010: 15–41).

Urban Planning, Roman

Jamie Sewel
Department of Archaeology, Durham University, Durham, UK

Introduction

Hundreds of towns were founded, expanded, and redeveloped across the breadth of the Roman Empire, many of which still survive as cities

today. Since the standing remains of the Romans' towns in Europe and the Mediterranean region are one of the strongest reminders of their urban-focused culture, the Roman town-building tradition has been a subject of scholarly interest for centuries. Urban planning involved incising the basic layout of a future town into the landscape, creating parameters for its physical development, although other processes are also associated with it. Since the designs of many such towns have survived in the archaeological record, scholars utilize this resource for interpreting the purpose and development of Rome's concept of the city.

Definition

Roman urban planning is the principles and practice employed in the founding, construction, expansion, and infrastructural maintenance of Roman nucleated settlements.

The physical definition and subdivision of a new urban space was to prepare it for construction: its fortifications, paved streets, or buildings. Thus, the study of Roman urban planning and the study of Roman urban architecture are partly intertwined. Traditionally, urban planning's strongest association is with an orthogonal grid of streets, possessed by many Roman towns. Regular street systems are the most obvious aspect of urban planning to have survived. Yet the founding of a new settlement also involved less archaeologically tangible processes, such as the establishment of a new urban population. After the initial founding, a town's physical development over time usually involved the periodical replanning of areas within it. The methods employed for planning towns were also used to design some nonurban or periurban settlements.

Historical Background

Ascertaining when the Roman practice of town planning began is hampered by the imprecision of the textual and archaeological sources. Although Rome itself grew to a great size, it never possessed an orthogonal grid of streets (Liv. 5.55). Particular areas of the city were replanned during its history, such as the major new fora projects initiated by Caesar, Augustus, and Trajan, yet an overarching unitary plan was lacking – a fact admitted by Roman authors. For the beginnings of Roman urban planning, one has to look instead to the settlements created in the wake of Roman territorial expansion. The first reference to Rome's involvement in the founding of a colony is for the late sixth century BCE. As many as 16 of the so-called Latin colonies are reported to have been created before the mid-fourth century BCE, but they were seemingly founded with the involvement of other Latin city-states. From an archaeological perspective, the sites associated with these early colonies demonstrate settlement histories stretching further back in time than the colonial foundation dates furnished by the written sources. In this sense, the founding of a colony by Rome before the second half of the fourth century BCE appears not to have involved the creation of a new settlement, but rather the sending of colonists to an existing one. Archaeological evidence does not currently support a systematic redevelopment of these settlements' urban centers immediately after, and as a consequence of, becoming colonies.

There is insufficient archaeological data to determine confidently which Roman settlement was the first to be constructed from scratch (*ex novo*). A small coastal fort at Ostia may have been the first (see below), but the first colonial town known to be founded by Rome alone on a site with no known pre-Roman settlement is Fregellae (328 BCE). It was orthogonally planned and placed on the banks of the river Liri to counteract the contemporary Samnite threat. At least by the second half of the fourth century BCE, then, Rome was employing surveyors to plan her new settlements.

Scholars have long debated the source of Roman urban planning practices. Some Bronze Age settlements of the *terramare* cultures on the Po plain were laid out orthogonally, and this prompted a theory, no longer upheld, that this represented the origins of formal town planning on the Italian peninsula. In the 1950s, F. Castagnoli proposed that the orthogonality of Rome's colonies (and that of Etruscan

settlements) was derived from the advances made by Hippodamos of Miletus (Castagnoli trans. 1971). This Greek urban planner is known to have been involved in the redevelopment of Piraeus, Athens' harbor town, during the fifth century BCE (Arist. *Pol*. 1267b 24–1269a 29). Although the term, "the Hippodamian plan," is still synonymous with the orthogonal street systems of classical antiquity, it is misleading. Orthogonality was employed in Greek urban contexts before Hippodamos was born, as seen in the Archaic Greek colonies of southern Italy and Sicily. The Etruscans seem to have adapted these ideas, reflected in the early fifth-century-BCE street plan of Marzabotto (Bentz and Reusser 2008). Most recently, the ancient Latin town of Gabii has been discovered to have had a regularized street plan (Becker et al. 2009). The close proximity of Gabii to Rome suggests that the Romans could have learned these methods considerably earlier than previously thought. Yet what is lacking is a proven, planned Roman settlement predating the later fourth century BCE.

Early Roman town planning has much in common with contemporary Hellenistic practices, suggesting that concurrent developments in the broader Mediterranean and in Italy were influential (Sewell 2010). Regularized settlements were being founded on the Italian peninsula in Bruttium and Lucania in the late fourth century BCE (Osanna 2009). The old Etruscan centers and perhaps some in Latium were founding small fortified centers in their territories. On a macro-level, this was the most dynamic period for urbanism in the eastern half of the Mediterranean, with the founding of hundreds of cities by Alexander the Great and his successors. A corresponding increase in the quantity of itinerant experts in urban planning must have resulted. This situation probably contributed to the dissemination of contemporary, town planning practices among the urban cultures of the Mediterranean at this time, including the Romans. Although some Greek concepts are manifest in the earliest examples of Roman urban planning after 338 BCE, others are not. Some older Italic conventions were also adopted. Additionally, the Romans were also innovative from the beginning, employing conventions not seen in the settlement forms of other urban cultures.

Many new towns were founded by Rome on an already highly urbanized Italian peninsula during the republic and under Augustus (Gros and Torelli 2007), and many annexed, existing settlements were subsequently replanned. In the wake of Rome's dramatic territorial expansion across the Mediterranean and Europe between the later third century BCE and the first century CE, in many cases, a settlement model was created with which Rome had most experience: a network of urban centers administering territorial units. Consequentially, the areas of the empire which are closely associated with Roman urban planning are those provinces to which Rome brought the concept of the city for the first time.

Key Issues/Current Debates

Sources

Urban archaeology provides scholars with most of the available evidence on Roman urban planning. Archaeological evidence from the majority of Roman towns is derived from the excavation of only a small percentage of their total surface areas. Many have modern settlements situated above them, prohibiting extensive archaeological investigation in the long term. Thus, the plans of Roman towns created by archaeologists often involve extensive hypothetical reconstruction. When conditions are favorable, modern remote sensing techniques can reveal an abandoned town's plan (Fig. 1), but to establish how the plan developed over time without accompanying excavation is an interpretational challenge.

Few ancient textual sources relate to Roman town planning. An overview is provided by Vitruvius (1.4–7; Rowland and Howe 1999) writing in the Augustan period, who discusses how to choose the site of a new town, the planning and construction of the city wall, the laying out of the streets, and the allocation of public spaces. He also describes some of the technical procedures for the laying out of a city. A surviving collection of surveying manuals, the *Corpus Agrimensorum Romanorum*, was probably compiled in the fifth

Urban Planning, Roman, Fig. 1 Falerii Novi. Reconstructed town plan based on the interpretation of a magnetometry survey (Millett 2007: 72, Fig. 1. Reproduced with permission from M. Millett and the Journal of Roman Archaeology)

century CE (Campbell 2000). Although it deals primarily with the procedures and issues related to the division and marking of land outside cities, similar techniques were employed by those engaged in planning urban space. An important testimony from the sixth century CE is provided by the treatise of Julian of Ascalon who set down regulations governing the design and replanning of houses to ensure the continued urban vitality of existing cities (Hakim 2001). Many surviving inscriptions refer to building projects that contributed to the physical development of towns over time.

The Process of Urban Planning

During the Roman Republic, the founding of colonies was overseen by three commissioners (*tresviri coloniae deducendae*), often high-ranking politicians who were responsible to the senate and the people of Rome (Gargola 1995). Some written sources refer to the commissioners being present at the site of the new settlement. The great military leaders of the Late Republic founded many colonies for the veteran soldiers of their wars, although this could involve settling them in an existing town and elevating its status to that of a colony. During the Imperial Period, emperors and their agents founded new colonies. Provincial governors might also have encouraged urbanization. Yet there were other forms of Roman town than just colonies, and for many of them, it is unclear who instigated and oversaw their foundation.

A number of interdependent factors influenced the choice of a new urban site. Curiously, our chief contemporary literary source, Vitruvius, discusses only one consideration: how healthy a site was in terms of its soils, winds, and nearby bodies of water, the qualities of which, in his view, could either be salubrious

or lead to illness. Today, it is believed that many other factors were influential. Colonies were frequently founded in newly conquered territory, and, during the republic, defensible positions were often favored to protect the urban population from potentially hostile neighbors or invaders. When no high ground was available, natural water courses could be exploited to provide protection to a town's perimeter. During the imperial period, low-lying sites were chosen even when elevated terrain was available. This is not only a sign of more peaceable times but could also be due to the benefits brought by easy access to long-distance communications routes. With the Romans' habit of building public roads and their utilization of navigable rivers and natural harbors, towns became nodes in the empire's transport network. New Roman foundations were often situated directly within or nearby to existing native settlements, effectively replacing them – true during both the republic and the empire. The Latin word *colonia*, although it came to be more closely associated with a particular legal status during the imperial period, originally signified a "settlement of cultivators," indicating that the presence of adjacent land suitable for tilling was often a prerequisite. Towns could also be sited in relation to the commercial exploitation of other natural resources such as metals or building materials. Freshwater was a basic requirement for a new town, and securing its supply would have influenced the decision of where to locate it.

Little is known about those who were involved in the planning of the new settlement. In reference to a colonizing project, Cicero (*On the agrarian law* 2.32; Freese 1930) mentions surveyors, architects, clerks, secretaries, and criers. Surveyors who were responsible for establishing the holdings in a town's territory probably also created the street system. Hyginus Gromaticus (*Constitutio limitum* T 144; Campbell 2000) advises setting up the central right-angled intersection of a new system of land division for a colony either in or as close to the town as possible, so that the orientation of the street system and the boundaries of the agricultural land is the same. This method was apparently applied for the planning of Ammaedara (Haïdra) in Africa. During the imperial period, experts from the Roman army could also be involved in urban planning.

The founding of a town could be initiated by the sacred act of taking the auspices (interpreting the flight of birds) and the *sulcus primigenius* (a ritual pulling of a plow) to demarcate the limit of the future town. A monumental definition of this perimeter could be created with the construction of a city wall, an essential element of Roman towns during the republic. Many new towns of the imperial period were originally not given fortifications. Walls were expensive to construct due to their manpower requirements and the time they took to build. It was the army's role to provide security on the empire's borders. In the peaceful inner areas, there is some suggestion that city walls were a privilege conferred by imperial favor.

Some of the tools used for surveying are known (Adam trans. 1994), such as the *groma*, a pole driven into the ground, on top of which was attached the center of a horizontal cross of four perpendicular arms of the same length. Right angles were established with this instrument. An example was recovered at Pompeii in the House of Verus. Measuring rods ten Roman feet in length, the *pertica* or *decempeda*, were also used, and the lines thus created must have been marked on the ground in some way until construction began.

In descriptions of Roman town plans by archaeologists, the terms *decumanus maximus* (main east-west street) and *cardo maximus* (main north-south street) are often employed. This terminology is taken from the writings of the Roman surveyors and was applied to the main intersecting straight axes of land division. It was long assumed that these terms were also applicable to urban streets, and an actual example of an urban *decumanus* is known from two inscriptions from the Latin colony of Aquileia (*Insc. Aq.* 842 and 3495) in Italy. This town's plan is known not to be orientated according to the cardinal points (Fig. 2), indicating that these terms were applied even when the streets were not so aligned. Roman urban street systems could be strictly aligned east-west and north-south, but the majority were not. What factors determined the orientation of a street

Urban Planning, Roman, Fig. 2 Aquileia. Partially reconstructed town plan. (Adapted from Lackner 2008: 335)

grid is often difficult to establish. Vitruvius recommends orientating the grid obliquely to the prevailing winds to avoid ill health among the urban inhabitants. Practical considerations such as the site's natural topography could play a role. Some towns were founded along the routes of public roads, the axis of which could influence that of the urban street system.

Archaeologists normally apply the Latin term *insula* (island) to describe the rectilinear blocks framed by streets that made up the town. In antiquity this term was specifically used to denote large apartment buildings, common in Rome from the Augustan period, well-preserved examples of which may be still seen at Ostia. The primary Roman units of measurement used in surveying were the *pes* (Roman foot) and the *actus* (120 ft). Other forms of unit from specific regions of the empire were employed locally. It is often difficult for archaeologists to reconstruct the units employed on a specific site due to inaccuracies in the original surveying. Although the reproduced plans of Roman towns often make them appear to be regular, on the ground there are nearly always discrepancies in the dimensions of each city block.

Very little is known about other aspects of the planning process which were probably much more challenging for the founders than marking straight lines on the terrain. Above all, urban planning was about giving structure to a built environment for a new population, usually comprising thousands of individuals. Founders of Roman colonies and their agents were responsible for establishing the new population at the site, distributing land to farm, and probably also allocating plots destined for houses in the town. This must have been a huge organizational challenge and a stressful process for the colonists who would have needed temporary shelter until their homes were built and food supplies until their first harvest. Founding towns was also a costly business. Finance needed to be managed, and labor and building materials needed to be procured. At least by the Late Republic, public building was often undertaken by contract with complex, legally binding clauses. Time pressure was also an issue. During the republic, the tenure of colonial commissioners is known to have been three years, although they probably remained as patrons of the new town in the long term. Thus, archaeologically speaking, most of the processes involved in urban planning are virtually invisible, resulting in a disproportionate modern emphasis on the physical layout of Roman settlements in publications concerned with urban planning.

Planning Characteristics of Roman Towns

As discussed below, the form of Roman towns differed according to region. No two were the same, and they varied greatly in size, yet certain planning conventions were used repeatedly. Orthogonality is a characteristic of most *ex novo* towns and was usually applied to major extensions of existing cities, such as Pergamon in Asia Minor. Annexed settlements could be replanned with regularized grids, but some continued to develop with no major change to their original, unordered layout, such as Glanum in Gallia Narbonensis, Thuburbo Majus in Africa (Fig. 3), or indeed Athens. Square *insulae* (city blocks) have a strong Roman association (Fig. 4), but this should not be over emphasized. Perhaps the Latin colonies of Placentia and Cremona (founded originally in 218 BCE) were the first to have square city blocks, but rectangular *insulae* continued to be common in Roman planning. A walled town did not always have a street system filling its entire intramural space, but when it did, normally a street ran around the entire inner face of the wall (Figs. 3, 4, and 5).

Orthogonally planned cities usually had the forum placed so that the main streets running from the main gates would converge on it (Figs. 1, 4, 5, and 6), but this did not always correlate with the town's geometric center. During the republic, elongated rectangular fora were the norm (e.g., Falerii Novi and Aquileia: Figs. 1 and 2), with more variation seen in the imperial period, including near-square examples (e.g., Thuburbo Majus and Timgad: Figs. 3 and 4). On sites with pronounced terrain, the forum was usually placed on level ground, and an elevated position was often favored (in stark contrast to Greek practice). Multiple fora are known to have existed in some towns, although additional fora were usually created some time after the initial foundation. During the republic, there is some sign that towns were planned with areas reserved for houses of its ruling class situated near the forum.

Fora developed over time to have buildings related to commerce and local government lining their borders, usually with some religious foci (Gros 1996). During republican times, some

Urban Planning, Roman, Fig. 3 Thuburbo Majus: plan of the Roman city. Example of an irregular town plan. (Adapted Alexander et al. 1980: Plate 34)

towns had uniquely sized *insulae* placed along the edges of the forum intended for its future public architecture. Often *tabernae* (shops) were built along a forum's flanks, and, from the Late Republic onward, a *macellum* (market) could be found nearby. The political function of the forum is reflected in the fact that it frequently possessed some form of political assembly place, such as a *curia* (senate house), and it has been argued for several Roman towns that voting took place on their fora. Thus, the presence of a forum is taken to reflect the ability of a community to run its own affairs.

In a town situated on particularly pronounced terrain, often the highest points were reserved for its most important sanctuaries and sacral architecture. If founded on more level ground, major temples could be placed near or on the forum instead. A forum dominated by a large axially placed temple at one end started to become a feature of some Roman foundations from the second century BCE in Italy and Spain. Under the emperors, starting at Rome with the Forum of Caesar, this convention took on a new impetus. The character of the forum changed by becoming pedestrianized and a location for emperor veneration. An axially arranged forum with a temple at one end became common in many of the Western Provinces. More common still on western fora from the Augustan period onward was a basilica, a multifunctional hall with architectural origins in the second century BCE, associated particularly with the dispensing of justice, commerce, and local government. It was sometimes situated

Urban Planning, Roman, Fig. 4 Timgad (Thamugadi): actual state of remains. (Adapted Gros and Torelli 2007: 370, Fig. 223)

axially opposite the main forum temple, as at Bavay, Trier, and Amiens. Axiality in architectural compositions is generally a trait with strong Roman associations.

Similar to Greek planning practices, some basic urban zoning was created by town planners. The largest fraction of a city's surface area was intended for domestic architecture. Communal

Urban Planning, Roman, Fig. 5 Ostia. Hypothetical reconstruction of the original *castrum*. (Adapted from Brandt 1985: 43, Fig. 4)

Urban Planning, Roman, Fig. 6 Aosta: Reconstructed town plan. (Adapted from Gros and Torelli 2007: 244, Fig. 133)

spaces were defined from the start, such as streets, the forum, and sanctuaries. Areas outside the city were reserved for necropolises, but it is unclear whether they were assigned during the initial planning. Cities could develop to have areas dominated by facilities for industrial production, but there is little sign such zones were set aside from the start. Although commerce is strongly associated with the forum, anyone who has visited Pompeii is aware that shops and bars are found in

many areas of the town, and they tended to develop along the busiest streets over time.

Urban Planning and Military Installations

It is unlikely that the Romans learned how to plan towns from their experience in creating temporary military camps because their first planned towns predate the tradition of the planned camp. Most Roman military installations have rectilinear forms for the same reason some Roman towns do: it is an expedient solution to building on level terrain. Yet the situation may be more complex, since among the candidates for the first *ex novo* planned settlement built by the Romans is Ostia, a rectilinear, permanent coastal fort (Fig. 5). It may be described as a fort due to its small size (2.44 ha), its defenses, and a lack of a forum. Most scholars believe it dates to the mid-fourth century BCE or later, and it was a colony of Roman citizens, placed to defend the coast near Rome. As many as ten similar citizen colonies were subsequently built on coastal stretches of the *ager Romanus* (Roman public land) before the end of the third century BCE. From the early second century BCE onward, the character of the citizen colony changed. New examples were much larger and had a forum, making them small towns. An example is Potentia (184 BCE) in *Picenum*. Although nearly 18 ha in size, just like its smaller predecessors it was rectangular in shape, probably with a gate on each wall and a central intersection of the streets leading from them. This design continued to be used, as manifested in the Augustan colonies of Aosta (Fig. 6), Barcino (Barcelona), and Turin. In turn, this form of planned settlement has similar design characteristics to the "playing-card" design of auxiliary forts and legionary fortresses. Timgad, a second-century-CE colony founded for military veterans and planned by the *Legio III Augusta*, has a design seemingly influenced by that of a military base (Fig. 4).

Similarly, planned forts and fortresses could themselves become the basis for towns in the Western Provinces when the army vacated them. In Britain, for example, the street system of the legionary fortress at Colchester became the core of a colony for veterans in the first century CE (Fig. 7). After the army had withdrawn from the legionary base at Wroxeter and demolished it, its street system was incorporated into a civilian settlement which became the *civitas* capital (see below) of the *Cornovii*.

Urban Planning Outside Towns

Periurban settlement is known to exist around many Roman towns (Goodman 2007), but it usually developed with little respect to the alignment of the urban street system (Fig. 3). Some orthogonally planned extramural settlement is known, however, such as that in front of the south gate of the *Oppidum Ubiorum* (which later became Roman Cologne), laid out soon after the town's foundation. Similarly, many secondary settlements in the territories of administrative urban centers developed without regularized street systems. A few were planned orthogonally, such as *Epomanduorum* (Mandeure) in Gaul (Fig. 8), which may have been founded through private initiative. It eventually covered an area of 120 ha and possessed monumental public buildings.

The Three-Dimensional Development of Urban Plans

The physical evidence for urban planning is provided by the archaeological remains of structures and streets subsequently built in conformity to the surveyors' lines. After the initial surveying was complete, filling an urban plan with buildings could be a prolonged process. At the Latin colony of Cosa, for example, founded in 273 BCE, no house yet found predates the second century BCE! Public buildings were expensive to erect and depended upon available funds, meaning that they were usually constructed individually over time. From the second century BCE onward, urbanization occurred at a more rapid pace. Although towns could use their public finance for building projects, the process was boosted by a new and rapidly growing convention among the elite to donate their wealth for the good of the public. Euergetism (public benefaction), as it is known, became a driving force for the creation of public buildings, streets, aqueducts, and other amenities in towns across the empire.

Urban Planning, Roman, Fig. 7 Colchester: plan of the fortress (above) and its development into the first colony (below) (Crummy 1993: 36, Fig. 3. Reproduced with permission of P. Crummy and the Council of British Archaeology)

Large building projects could transform a town's plan over time. Once all the available empty spaces of the original plan had been filled, new houses and public buildings could be constructed outside the town, as demonstrated at Timgad (Fig. 4). A lack of vacant urban space is one of the explanations why many large structures, such as amphitheaters, were located on the

Urban Planning, Roman, Fig. 8 Mandeure: reconstructed plan of a "secondary agglomeration." (Adapted from Petit et al. 1994: 91, Fig. 3)

edge of, or just outside, a town's limits. The continued growth of a town was usually not limited by the constraints of its original planning unless it was situated on mountainous terrain. At *Augusta Treverorum* (Trier), a new wall circuit was built toward the end of the second century CE which increased its original surface area from 80 to 285 ha. There are also many instances of intramural areas being replanned to make way for new building complexes. This is most dramatically illustrated at Rome through the building projects of the emperors. The baths of Trajan, for example, created after 104 CE, had a perimeter enclosing an area of more than 10 ha, built directly on top of the *Domus Aurea* (the palace of Nero). Smaller scale projects reshaped urban centers in Italy and the provinces, mutating their original plans. The dynamism of Roman towns is reflected in these patterns of abandonment, replanning, changing property boundaries, and new construction. Towns could also contract, a phenomenon particularly well documented in Gaul and Greece in late antiquity, where many new defenses were thrown up, encompassing a severely reduced urban area.

Efforts to control cycles of abandonment and reconstruction already start to become apparent by the first century BCE. In the *Lex Tarantina* (Crawford 1996: 304, 307), it states that no building should be demolished unless a promise is made to the town's chief magistrate to rebuild it. Provincial governors could order owners to repair buildings, and especially appointed officials (*curatores*) could be allocated to cities in the west for up to 10 years with the task of restoring their urban vitality (Laurence et al. 2011). The recycling of urban structures became widespread in late antiquity, particularly apparent in the dismantling of pagan sanctuaries and the reuse of their building materials in new churches. A surviving treatise by Julian of Ascalon from the sixth century CE is a compilation of guidelines for the construction of houses (Hakim 2001). He focuses on the general upkeep of the built environment and conflict avoidance among neighbors, dealing with issues such as fire prevention and height restrictions during new construction.

International Perspectives

Although some generalizations may be made about Roman urban planning, pronounced regional variations are apparent in the form, size, and development of towns across the empire. Local traditions clearly had an influence, but establishing why particular differences manifest themselves in distinct regions is often challenging. Due to the size of the Roman Empire and its urban diversity, publications relevant to urban planning tend to focus on individual sites, provinces, or regions.

Roman town planning is more strongly associated with Italy and the Western Provinces because more settlements were founded there than in the Roman east, much of which was already urbanized when incorporated into the empire. In Greece, large-scale Roman interventions there were few: Caesar refounded Corinth as a Roman colony in 44 BCE; Patras became veteran colony under Augustus, who also founded a new city, Nikopolis in Epirus, after the battle of Actium, necessitating the citizens of nearby *poleis* to abandon their ancestral homes to resettle in the new city. Colonies were also founded in Macedonia, Asia, Syria, and Pisidia by Augustus. Towns continued to be founded, sporadically, such as Antinopolis in Egypt by Hadrian, and the new Roman capital Constantinople begun in 324 CE on the site of former Byzantion. Many existing eastern cities were transformed through planned urban expansions and smaller replanning projects associated with large-scale building programs. At some sites, such as Gerasa in Jordan and Aphrodisias in Caria (Turkey), the physical remains of the Roman period dominate the archaeological record. The character of the public spaces and domestic and monumental architecture of the east under Roman rule was often strongly influenced by local traditions, and the resulting conceptual fusion is a major theme in scholarly literature. Many new planned towns in the previously un-urbanized Danubian provinces were founded on or near bases of the Roman army.

In the Roman west, great numbers of colonies and other forms of urban centers were founded as a consequence of Roman conquest. Some areas, such as North Africa, southern Gaul, and the Iberian coastal areas had already been partly urbanized by the Greeks and the Phoenicio-Punic cultures. The earliest western Roman foundations were in these regions, such as *Italica* (206/205 BCE) and *Narbo* (118 BCE), although little is known about their early development. From the Augustan period onward, towns were founded in previously un-urbanized areas, such as Britain, Spain, and *Gallia Comata*. Territorial units called *civitates peregrinae* (denoting that their inhabitants were not Roman citizens) are most strongly associated with the previously un-urbanized areas of the empire, and those in the west have been well studied. They were loosely based on pre-Roman ethnic boundaries and were often administered by urban centers, the creation of which often involved some form of urban planning. Yet these towns, the *civitas* capitals, were not founded systematically by the Romans but came into existence over time through a variety of processes.

Future Directions

With the increasing use of remote sensing techniques to record the plans of abandoned towns, going forward, the body of evidence for urban planning is sure to increase, encouraging comparative studies; a good example of which is the analysis of the plans of *Falerii Novi*/*Falerii Veteres* (Millett 2007). The developmental trajectory of Roman urban planning practices and the reasons behind regional variations might thus be elucidated as a consequence. It should also be possible to explore further the relationship Roman towns enjoyed with the territories they administered. For example, a recent study has suggested that the replanning of towns in northern Campania was accompanied by changes in the settlement patterns of the territories associated with them (Rescigno and Senatore 2009).

Urbanism in the Ancient Near East

Bleda S. Düring
Faculty of Archaeology, Leiden University, Leiden, The Netherlands

Introduction

The earliest urbanization on the globe occurred in the Near East in the context of a broader cultural transformation that led to the emergence of the first complex societies. The historical significance of these developments, which included the appearance of class societies and the advent of writing, cannot be overstated. Despite their historical importance, cities in Mesopotamia and the wider Near East remain relatively poorly understood. The reasons for this situation are first, conceptual; second, methodological; and third, political. In recent years, however, remarkable steps forward have been achieved in the study of urbanism in the ancient Near East. This brief essay

will summarize the current situation in the archaeology of urbanism in the Near East and will discuss possible ways forward.

Definition

Defining urbanism is a complex issue. Diverse answers are possible (Smith 2003) to the following simple question: What is a city? First, in some cases "city" is a legal status defining a particular form of administration within a state. Second, cities can be political institutions, as, for example, in the Greek *polis*. Third, a sociological characterization of cities focuses on the structure of social interactions: city dwellers interact as strangers with little solidarity. Fourth, a geographical definition is one in which cities are central nodes that can only exist in relation to a hinterland of smaller villages that supply it with goods and food in exchange for urban services. In addition, the urban settlement harbors full-time specialists of various types, has particular urban facilities, and is marked by zoning of activities.

In the study of urbanism in the ancient Near East, both the sociological and the geographical perspectives on urbanism are important, whereas legal and political characterizations have been less influential (Smith 2003; Marcus and Sabloff 2008; Emberling 2015). The famous ten-point list of urbanism proposed by Vere Gordon Childe (2004: 112–115) is in fact a geographical definition of cities put together on the basis of his knowledge of the ancient Near East. Given the diversity of urban settlements, scholars working on the issue in recent years do not typically offer this type of trait list definition anymore, but they do adhere to a qualitative differentiation between cities and their hinterland (e.g., Emberling 2015).

Key Issues/Current Debates/Future Directions/Examples

Classifying settlements as urban is not a neutral act. The word "city" is etymologically linked to "civilization," and when archaeologists claim urban status for an archaeological site, civilization is often implied (Childe 2004: 108). Many archaeologists have argued that cities and civilizations first emerged in the Neolithic, at sites such as Jericho and Çatalhöyük, which where substantial settlements encompassing several thousands of people (Gates 2003: 18–28). These interpretations are problematic, however, given the nature of settlements such as Jericho, Çatalhöyük, and other large Neolithic settlements such as Abu Hureyra and 'Ain Ghazal. None of these large sites are surrounded by associated subsidiary settlements, and none of them have evidence for full-time specialists, central facilities, or zoning of activities, and it is for this reason that Hole (2000) argued that size is not an index of complexity in the Neolithic.

It is only in the fourth millennium BC, during the so-called Uruk period in Mesopotamia, that we can document the rise of the first truly urban settlements in the Near East. In the course of the Uruk period, the size of the largest settlements increases by a factor 20, from about 10 ha to 200 ha, and we see the rise of settlement systems consisting of large centers with associated smaller villages (Pollock 2001), and the emergence of monumental architecture within the urban centers, most spectacularly at the eponymous site of Uruk (Nissen 2015). The most popular explanation for the urbanization processes and the accompanying demographic changes focuses on the idea that in the Uruk period, the southern alluvium was at an ecological optimum during which very high agricultural yields could be obtained with relatively little effort and which could be supplemented with aquatic resources from nearby marshes (Algaze 2008).

Despite the importance of the Uruk period in the history of the Near East, we know relatively little about the urban settlements concerned. Our knowledge of the period derives from three sources: Robert McC. Adams' large-scale surveys in the 1950s–1970s (Adams and Nissen 1972), German surveys of the city of Uruk in the 1980s (Finkbeiner 1991), and early excavations at sites such as Uruk, which focused heavily on the monumental buildings (Eichmann 1989). Political

developments within Iraq have precluded further survey work and excavations of early urban centers, with the result that we know very little about issues such as the density of occupation, the presence of workshops, and whether there was zoning of activities in these settlements. In short, we know little about the nature of the urban economy and society in this period.

In recent decades it has become clear that in northern Mesopotamia urbanization also occurred that was at least as early as that in the southern alluvium. This is best documented at site such as Tell Brak, Tell Hamoukar, and Arslantepe (Oates et al. 2007; Al Quntar et al. 2011). Survey data suggest that these sites reached considerable sizes, 130 ha (Tell Brak) and 300 ha (Tell Hamoukar), and excavations have produced evidence for monumental buildings and long-distance trade. It should be noted, however, that monumental buildings and long-distance trade are well documented at earlier sites, such as Ubaid period Gawra (Rothman 2002), and that we do not really know what the large spreads of surface material at Hamoukar and Brak represent. The research projects investigating this issue were cut short by the Syrian civil war. Thus, unfortunately, we know relatively little about the spatial layout and activities that took place within these cities, and thus our understanding is limited, as it is in the south. Interestingly, the ecological optimum argument that has been used to explain the rise of urban communities in the south is less evident for the north, and there appear to be only a few large urban settlements in northern Mesopotamia. Further, the urban communities in the north disappear toward the end of the fourth millennium BC and only reappear around 2600 BC, whereas those in the south continue and flourish (Ur 2010).

The Early and Middle Bronze Age (3000–1600 BC) data for urban settlements are much richer than those available for the Uruk period. A large number of urban settlements have been investigated across Mesopotamia and in the Levant, including famous sites such as Ebla, Mari, Qatna, Eshnunna, and Ur. At the latter two sites, large-scale excavations undertaken in the early twentieth century AD have opened considerable exposures of residential and workshop areas, providing important data on the texture of urban life in Mesopotamia. Houses of various scales are found intermixed in dense neighborhoods, and there are small workshops, shops, and shrines mixed in between houses. A similar spatial subdivision in more or less equivalent neighborhoods consists of residences, shops, and workshops, and a central monumental area has been postulated for Mashkan-shapir, where an exemplary city survey was undertaken (Stone and Zimansky 2004). It has been argued that the mixed neighborhoods were occupied by kin groups in which client relations played an important role and that this type of agglomeration is comparable to that seen in traditional premodern Near Eastern cities (Stone 2007), although the latter are highly specific to a particular period in history and should not be construed as the timeless oriental city. These studies suggest that cities in the ancient Near East differed substantially from early modern cities of the west in social terms and that neighborhoods operated in ways not dissimilar to villages in the countryside. This point is also made by Steinkeller (2007) who argues that cities and villages differed relatively little in terms of economy and society.

In the Late Bronze and Iron Ages (1600–333 BC), the general understanding of urban cities in the Near East as composed of mixed neighborhoods with a central monumental complex surrounded by a city wall does not change much, although the size of temple and palace complexes depended on the power of the particular urban community. A Mesopotamian map of the city of Nippur dating to around 1500 BC depicts a city that meets these criteria in remarkably accurate proportions (Fig. 1). Archaeologically the best known example from this period is that of Ras Shamra (Ugarit), excavated on a large scale in the mid-twentieth century AD, for which Schloen (2001) argues that client systems along patriarchal lines were central to neighborhood communities.

In the Late Bronze and Iron Age, imperial capitals become prominent in the archaeological record. In cities such as Hattuša, Nimrud, Dur-Sharrukin, Nineveh, Babylon, and Persepolis, very monumental capitals were created with large palaces and temple complexes meant to inspire awe and act as testimony to the power of

Urbanism in the Ancient Near East, Fig. 1 The Nippur map on a clay tablet juxtaposed to a map produced of the city in the excavations (after Fisher 1905, plate 1 and Pedersén et al. 2010, Fig. 7). Redrawn by Joanne Porck

the empire (Harmansah 2012; Otto 2015). These cities were either new foundations or existing cities reengineered on a massive scale. On the whole these cities remain poorly understood as economic or social entities, despite very extensive research at, for example, Hattuša for over a century, because research has focused almost exclusively on the monumental elements of these cities.

The archaeological study of cities in the ancient Near East remains lopsided in that we know much more about palaces, temples, and ramparts than we do about cities as economic and social systems. This bias results from the entrenched notion in Near Eastern archaeology that monumental architecture is more worthy of investigation than residential and workshop areas. There are also methodological problems: it is no longer ethical to excavate at the scale and pace in which archaeologists uncovered entire neighborhoods and large monumental complexes in the early twentieth century AD. Finally, political developments have effectively closed of many parts of the Near East, including much of Iraq, Syria, and Iran, for archaeological research.

What, then, is the archaeological way forward for advancing our understanding or urbanism in the Near East? Obviously we need to balance the need for understanding urban settlements in their entirety and in their landscapes with the limited resources available, instead of focusing all our efforts on the monumental components of cities. Various projects have already shown what can be achieved with techniques such as systematic surface survey in combination with small test excavations, geophysical research, and remote sensing, and excellent results have been obtained at sites such as al-Rawda (Castel and Peltenburg 2007), Mashkan-Shapir (Stone and Zimansky 2004), Abu Salabikh (Postgate 1983), and Tell Taya (Reade 1973). Moreover, we need to know more about what happens in these cities, houses, workshops, industrial areas, etc. (Fisher and Creekmore 2014). Detailed studies mapping out artifact assemblages in excavated segments of urban settlements in combination with remote sensing technologies have a great potential to finally inform us about what happened in cities (Stone 2008; Fisher 2014; Nishimura 2014). Thus a powerful toolkit for better mapping the characteristics of ancient cities has developed over the past decades. Projects applying this toolkit have added a considerable amount to our understanding of urbanism with relatively limited resources. Now that various parts of the Near

East are once more accessible for archaeological research, such as southern and eastern Iraq, much of the Levant, Turkey, and Iran, it is to be hoped that more work along these lines will be executed in the years ahead and throw new light on ancient cities.

US Domestic Archaeological Heritage Law

Thomas F. King
Silver Spring, MD, USA

Introduction

To understand United States (US) law as it relates to archaeological resources, it is necessary to appreciate two facts.

First: The USA is a capitalist democracy made up of 50 more or less self-governing states (plus several territories and other jurisdictions) – each of which contains multiple semi-independent local governments. Besides these entities, there are over 500 American Indian tribes within the borders of the country, each of which is regarded in the law as a sovereign nation and many of which exercise control over land bases of varying scales.

Second: The US legal system circumscribes the rights of the federal government vis-à-vis those of the states, local governments, Indian tribes, and individual citizens (the last category strangely defined to include corporations). The rights of private property owners, though not absolute, are given considerable deference.

One result of these facts is that there is no generally applicable US law protecting archaeological resources or any other part of the environment. Instead, there are:

1. *Prohibition laws* designed to regulate access to archaeological resources on lands controlled by the federal government (and those held in trust by government for Indian tribes)
2. *Impact assessment and control laws* that more or less control the impacts of federal agency actions (and, less directly, the actions of other change agents under certain circumstances) on archaeological resources and other aspects of the environment
3. *Registration and documentation laws* that authorize and structure programs for the inclusion of archaeological sites and other places held to have heritage value on official lists and encourage documentation of their characteristics, but do not afford much if any protection for such places
4. *A complex mosaic of state*, *tribal*, *and local laws* designed to achieve similar purposes

In addition, there are government *programs* at various levels – generally grounded in some sort of law – designed to encourage and facilitate management of archaeological resources, among other environmental values.

Definition

Archaeological heritage law in the USA includes the law per se – that is, statutes enacted by the US Congress, state legislatures, tribal councils, and local governments – as well as regulations, standards, and guidelines issued by official bodies in accordance with those laws and executive orders

issued by the president, state governors, and the chief executives of tribes and local jurisdictions. Federal laws are codified in the United States Code (USC), where they are grouped into titles and sections. The Archaeological Resources Protection Act, for instance, is cited as 16 USC 470aa-mm, meaning Title 16 of the Code, Section 470, subsections aa through mm. Regulations are published in the Code of Federal Regulations (CFR), referenced by title and "part." For example, the regulations for implementing the Native American Graves Protection and Repatriation Act are cited as 43 CFR 10, that is, Title 43, Part 10 of the CFR.

Archaeology practiced under and in response to US cultural heritage law is widely and colloquially referred to as an aspect of "cultural resource management" (CRM) or even (very misleadingly) as identical with CRM in its entirety (see King 2005: 83–89, 2011: 1–3 for discussion).

The federal heritage laws – the focus of this discussion – have created, and are interpreted and administered by, several governmental bodies. These bodies structure the conduct of archaeology within the US government, so their roles need to be described at the outset.

Archaeology in the US Government

Unlike many other nations, the USA has no overall ministry or bureau that is responsible for the nation's archaeological resources or more broadly for its historic or cultural heritage. To some extent the National Park Service fills this role by managing many protected areas (units of the national park system) established in whole or in part to protect and interpret archaeological and historic sites. The National Park Service also manages "external" programs like the National Register of Historic Places, a list of formally evaluated significant archaeological, architectural, and historic sites, buildings, structures, landscapes, and other pieces of real estate throughout the country. It provides grants to help support the network of State Historic Preservation Officers (SHPOs) who administer historic preservation programs (including archaeology) in their states. Another general coordinative agency is the Advisory Council on Historic Preservation, a small independent agency that advises the president and congress on historic preservation (including archaeological) matters, oversees project review under Section 106 of the National Historic Preservation Act (NHPA; see below), and advises other federal agencies about their responsibilities under the same statute.

Each agency of the federal government in theory has its own program to implement NHPA and sometimes other cultural heritage laws, and those that manage substantial amounts of land usually emphasize archaeology – sometimes, unfortunately, to the exclusion of other aspects of heritage. The Smithsonian Institution and a few research bodies in other federal agencies conduct archaeological research for its own sake, but most agencies manage archaeological and other heritage resources as an adjunct to their core missions.

Under the NHPA, many of the functions involved in administering federal requirements pertinent to archaeology are carried out by State Historic Preservation Officers (SHPOs) and, on the lands of some Indian tribes, by Tribal Historic Preservation Officers (THPOs). Key functions carried out by SHPOs and THPOs include maintaining lists of identified historic properties (including archaeological sites), establishing plans intended to guide the identification and evaluation of such properties, and consulting with federal agencies and other change agents about actions that may affect such properties.

The Laws

As noted above, US laws relating to archaeology can be conveniently divided into three classes: prohibition laws, impact assessment and control laws, and registration and documentation laws.

Prohibition laws. The oldest of US archaeological laws is the Antiquities Act of 1906 (54 USC 32001-303), which forbade the excavation or removal of "antiquities" from federal and Indian tribal land without a permit from the relevant federal land managing agency. The law also

authorizes the president to withdraw federal lands from general use to form national monuments. After suffering a successful court challenge in the 1970s, the Antiquities Act was augmented by enactment of the Archaeological Resources Protection Act of 1979 (16 USC 470aa-mm; ARPA). This law does essentially the same thing as the Antiquities Act, but with reference to "archaeological resources," defined as things of "archaeological interest" that are over 100 years old. Section 3(d) of the 1990 Native American Graves Protection and Repatriation Act (25 USC 3001-13; 18 USC 1170; NAGPRA) similarly prohibits the disturbance of Native American (i.e., American Indian, Inuit, Aleut, and Native Hawaiian) human remains and cultural items on federal and tribal lands; NAGPRA goes on to establish a complex system for repatriating such remains and items, and those held by federal government agencies and federally assisted museums, to culturally affiliated tribes and groups.

Another prohibition law – though it does not directly prohibit anything – is the Abandoned Shipwreck Act (43 USC 2101–2106; ASA). The ASA establishes that the federal government owns abandoned shipwrecks in US waters, but also transfers title to them to the several states, which are expected to regulate access to them by archaeologists, sport divers, and commercial interests. Under the Sunken Military Craft Act (10 USC 113), however, the wrecks of military vessels remain US government property, and access to them is theoretically controlled by the various military services.

All the prohibition laws are aimed at controlling the individual (including corporate) citizen or noncitizen who might for some reason (e.g., research, wealth acquisition, recreation) intentionally disturb something of putative archaeological interest (or interest to the government). All directly or indirectly prohibit such disturbance by unlicensed persons, and some (like ARPA) prescribe standards and procedures for the issuance of licenses. Most only incidentally affect the operations of government agencies, if they affect such operations at all. In other words, under most prohibition laws relating to archaeology, the government prohibits *others* from disturbing archaeological resources but implicitly or explicitly allows *itself* to do so.

To the extent the prohibition laws are enforced – a difficult matter, given the scale of public lands in the USA to which most of them apply – they are enforced by land management agencies like the Bureau of Land Management, Forest Service, and National Park Service, as well as by agencies that manage lands incidental to their missions, such as the military services.

As a signatory to the 1970 UNESCO Convention on the Means of Prohibiting and Preventing the Illicit Import, Export, and Transfer of Ownership of Cultural Property, the USA makes efforts to control trafficking in antiquities across its borders, and ARPA includes a provision prohibiting interstate commerce in artifacts obtained in violation of its terms or those of other laws.

Impact assessment and control laws. With the expansion of government involvement in land use and industry that accompanied the Great Depression and World War II, citizens began to impress upon lawmakers the fact that government itself could do damage to the environment, including archaeological sites. The result, which continues to this day, has been a proliferation of laws, regulations, and guidelines, as well as international instruments, designed to assess and to some extent control the impacts of government actions.

In the USA, the general-purpose federal impact assessment law is the National Environmental Policy Act (42 USC 4321 and other sections; NEPA). Although the national policy promised by the law's title and articulated in its Section 101 is generally ignored, extensive regulations (40 CFR Parts 1500–1508) have been developed by the Council on Environmental Quality (in the Executive Office of the President) for implementing NEPA's procedural requirement. These feature preparation of a "detailed statement" of the environmental impacts of "major federal actions significantly affecting the quality of the human environment." Among the impacts to be assessed are impacts on "historic or cultural resources" (40 CFR 1508.27(b)(3)), which are widely understood to include (but not be limited to) archaeological sites. Importantly, NEPA requires consideration of the effects of

projects not only on federal and tribal land but wherever they occur in the USA (and to some extent elsewhere) – provided there is some federal involvement in them (via, for instance, federal grants, loans, loan guarantees, and licenses).

Interacting with NEPA compliance, Section 106 of the National Historic Preservation Act (54 USC 306108; (NHPA)) and regulations of the Advisory Council on Historic Preservation (ACHP) for implementing it (36 CFR Part 800) require federal agencies specifically to consider the effects of their actions on "historic properties," defined as places included in or eligible for the National Register of Historic Places. As discussed below, the register is a list of recorded and evaluated historic and prehistoric places that is maintained by the National Park Service. Any significant archaeological site can be eligible for the National Register (as may many other types of property), so compliance with Section 106 provides the rationale for funding thousands of archaeological surveys throughout the USA every year. The scope of Section 106 is similar to that of NEPA – it applies to potentially damaging projects wherever they are planned, regardless of land ownership, provided the federal government is somehow involved. Neither NEPA nor NHPA covers projects in which the federal government has no involvement.

Other sections of the NHPA prescribe additional federal agency responsibilities, authorize maintenance of the National Register, and provide for federal assistance to, and oversight of, SHPOs and THPOs.

Another federal law, known variously as the Archaeological and Historic Preservation Act and the Archaeological Data Preservation Act (54 USC 312501-08), requires that federal agencies finance the recovery of archaeological, historical, and scientific data threatened by projects they propose to conduct, assist, or license. NAGPRA also includes a "discovery" provision whose implementing regulations (43 CFR Part 10) effectively require that federal agencies assess the likely effects of their actions on Native American graves and cultural items on federal and tribal land, in consultation with Indian tribes and Native Hawaiian groups.

The collective effect of all these laws and regulations on the practice of archaeology has been considerable. In essence (though not explicitly), they require federal agencies – and through them, the many state, local, and private parties that benefit from federal financial assistance, contracts, licenses, and permits – to sponsor archaeological surveys wherever their projects may result in ground-disturbing activities. Such surveys are in theory conducted as parts of interdisciplinary studies to identify all kinds of environmental impacts under NEPA and as parts of "historic preservation" or "cultural resource management" (CRM) studies under Section 106 of NHPA. In practice, unfortunately, archaeological surveys are sometimes the only things done to identify "cultural resources" subject to effect by projects, ignoring resources that are not archaeological but may be of considerable cultural importance, such as culturally valued plants and animals, landscapes, and a wide range of more intangible aspects of the environment (King 2013: 3–6, 22–23, 126–128).

The assessment of impacts on archaeological sites and other aspects of the environment usually results in efforts to avoid, reduce, or otherwise mitigate effects that are adverse. Such efforts may be specified in documents prepared and adopted under NEPA and are routinely provided for in "memoranda of agreement" (MOAs) executed under Section 106 of NHPA. MOAs are based on consultation among the responsible federal agency, the SHPO and/or THPO, Indian tribes and Native Hawaiian groups, sometimes the ACHP, and other interested parties.

For archaeological sites, impact mitigation often involves "data recovery" – that is, rescue excavation or other forms of information retrieval, followed by analysis, reportage, and management of collections ("curation").

Registration and documentation laws. In the Historic Sites Act of 1935 (320101-0616 USC 461–467), congress authorized the National Park Service to identify and make records of historic places of significance in interpreting and commemorating the nation's history. Today such places are referred to as National Historic Landmarks; they are nominated through an exhaustive,

multilevel process of review and are said to be "nationally significant." When the NHPA was enacted in 1966, it created a more expansive National Register of Historic Places, including places of importance at the state and local levels. The National Park Service continues to maintain both the National Historic Landmarks list and the National Register, both of which include archaeological sites as well as historic buildings, structures, landscapes, and groups of properties referred to as "districts." The 1935 law also allowed the National Park Service to make permanent a Depression-era program that employed architects and draftspeople to prepare meticulous records of historic buildings. The Historic American Buildings Survey (HABS) survives to this day in the National Park Service and has cloned itself to create the Historic American Engineering Record (HAER) and the Historic American Landscapes Survey (HALS). All three programs (especially HAER) sometimes document archaeological sites.

State, *tribal*, *and local laws*. Many Indian tribes, states, and local governments have prohibition laws, some applying only to lands directly controlled by government (e.g., public parks and recreation areas) and some (including many Indian tribal laws) applying more broadly. Some jurisdictions have laws expressly prohibiting the exhumation of interred human remains, marked or unmarked, on all lands within their borders.

Most US states have their own environmental impact assessment and management laws, sometimes referred to colloquially as "state environmental policy acts" or SEPAs. Some have their own state equivalents of the National Register and provisions somewhat like those of NHPA Section 106 for addressing the effects of state-sponsored and state-regulated projects on historic places. Some tribal governments have enacted similar laws, as have a few local governments. Some tribes and local governments have set up their own archaeological, historic preservation, or "CRM" programs that conduct surveys, proactive preservation, and data recovery. Each state's, tribe's, and local government's laws and programs are unique to their promulgating jurisdiction; there is no consistency among sub-federal governments across the USA.

All the states and some tribes and local governments participate in the National Park Service's registration program by nominating properties, including archaeological sites, to the National Register. Some states, tribes, and local governments maintain their own registers as well, and some conduct documentation programs, often in cooperation with the HABS–HAER–HALS program of the National Park Service.

Generalizations. Generally speaking, the following can be said about US law relating to archaeology and archaeological resources:

1. There is no central government organization responsible for archaeology, though both the National Park Service and the Advisory Council on Historic Preservation fulfill some of the functions carried out by central cultural ministries in other countries. Federal land management agencies tend to have their own archaeologically oriented heritage programs, and State Historic Preservation Officers perform coordinative functions with respect to archaeological resource management in their respective states.
2. Excavating or otherwise disturbing an archaeological site on federal or tribal land for purposes other than the conduct of a federal, federally assisted, or federally licensed land-use project requires a permit from the responsible federal agency and/or tribe. Such permits are issued only to technically qualified archaeologists and require that work be done in accordance with research designs, adhere to established fieldwork standards, and produce reports. Recovered artifacts either remain the property of the federal government or are returned to tribes (or Native Hawaiian groups in Hawaii). These requirements are imposed under ARPA and NAGPRA. Similar requirements are often but not universally imposed by state and local governments on lands under their control, under their own laws; some Indian tribal governments impose similar and sometimes more restrictive requirements on tribal lands. Excavation and other disturbance

of sites on private land are mostly unregulated, but it is illegal to disturb graves in many jurisdictions, and excavations on private land that are carried out with federal assistance (for instance, under a research grant from the National Science Foundation) are regulated (in theory at least) under NEPA and NHPA.

3. Construction and other land-use projects (mining, forestry, road construction, energy production, etc.) on federal land, or on any other land with federal assistance or permits, must be subjected to impact analysis of some kind under NEPA and must be the subject of review and consultation under Section 106 of NHPA. Archaeological surveys are often done as part of the impact assessment process, along with studies to identify and evaluate historic buildings, structures, neighborhoods, landscapes, and other resources. Multiparty consultation on the effects of such projects usually leads to agreements about how adverse effects will be mitigated; this often involves archaeological excavation. Surveys and data recovery operations, like other kinds of environmental impact assessment and mitigation, are usually financed by project proponents.
4. Archaeological sites are routinely included in the National Register of Historic Places, although the cost of preparing nominations and the fact that nomination does not give a place any particular protection tend to discourage this practice. Under Section 106 of NHPA, the same consideration is given to a place that simply meets the criteria for inclusion in the register as to one that is actually included. Some state and many local laws, however, require that attention be given only to impacts on places actually included in the National Register or a state or local equivalent.
5. Artifacts and data recovered from federal and tribal land remain the property of the federal government or the tribe from whose land they came and for the most part must be cared for in accordance with government-wide curatorial policies issued by the National Park Service (36 CFR Part 79). An exception is made under NAGPRA for Native American human remains and cultural items, which are repatriated to culturally affiliated tribes or groups, who may manage them as they think best. Ownership and control of artifacts found on nonfederal, non-tribal land are determined in accordance with whatever state and local laws apply. As a general rule, and with the general but not invariable exception of human skeletal remains, archaeological material found on private land remains the property of the private property owner.

Key Issues/Current Debates

Most of the laws under which archaeological sites are managed in the USA were drafted and promoted by environmentalists, historic preservationists, and other non-archaeologists, but over the decades archaeologists have adapted to the laws and sometimes become dominant in their interpretation, particularly in the federal land management agencies. This has generated concern about whether implementation of the impact assessment and control laws has come to be biased in favor of archaeology at the expense of other types of historic properties and more broadly defined cultural or heritage values. Indian tribes and Native Hawaiian groups are particularly vocal in their opposition to an overly archaeological approach to management of their heritage.

A widespread, rather mindlessly accepted equation of "cultural resource management" (CRM) with archaeology – particularly by academic institutions where the latter is taught – has led to confusion about just what the laws are intended to protect (see King 2005, 2009, 2011: 534–549; Sebastian and Lipe 2011).

Implementation of the impact assessment and control laws has created a multibillion dollar cultural resource management industry dominated by for-profit consulting firms that perform archaeological, historical, and architectural surveys, studies, and impact mitigation work like rescue archaeology under contract. The quality of this work, its value as research, its usefulness to the public, and its cost-effectiveness are sometimes questioned by a range of interests, including members of congress, development firms,

nongovernmental organizations, Indian tribes, and archaeologists themselves. The fact that most impact assessment and mitigation work is done by contractors for the proponents of the very projects that threaten or destroy archaeological sites and other aspects of cultural heritage raises questions about whether and how much archaeologists have become shills for development interests (see King 2009).

The boom in archaeological fieldwork under the heritage laws has greatly exacerbated the problem of what to do with fieldwork's products – particularly recovered artifacts and other materials. The poor fit between burgeoning collections and limited curatorial facilities – for which the term "curation crisis" was coined in the 1990s (see Childs 1995) – remains unresolved, although the US Army Corps of Engineers and others are working hard to address it.

In the 1980s and 1990s, there was considerable conflict between archaeologists and indigenous groups, including Indian tribes and Native Hawaiians, over the treatment of ancestral human remains and associated cultural items. Although the enactment and more or less systematic if often highly bureaucratized implementation of NAGPRA has ameliorated this conflict, treatment of the dead and their belongings, and of ancestral artifacts in general, remains a prickly subject (see Thomas and Deloria 2001; Watkins et al. 2008). At the same time, NAGPRA has forced the development of relationships between archaeologists and tribes that would doubtless never have evolved otherwise. The late Hester Davis (2010: 191) asserted that NAGPRA "has changed the world of American archaeology . . . forever," by altering the power relationships between archaeologists and indigenous communities and requiring the former, at least, to adapt to new realities. Meanwhile, conflicts continue to arise from time to time not only between archaeologists and Native Americans but between archaeologists and groups whose ancestors are not embraced by the protections of NAGPRA, such as the descendants of enslaved Africans (c.f. Hansen and McGowan 1998).

Offshore, the treatment of shipwrecks and other submerged archaeological resources continues to be a contentious issue. US archaeologists, like their compatriots in the United Kingdom and elsewhere, tend toward reflexive revulsion at the damage ostensibly done to such resources by "treasure hunters," even when such damage is controlled through application of high-quality archaeological methods. As Sean Kingsley (2010, 2011: 223–244) has detailed, the same archaeological communities seem less concerned with the far more extensive destruction of wrecks wrought by modern deepwater fishing.

Academic archaeology in the USA tends to ignore CRM or to treat it as an uninteresting low-grade specialization in which its second- and third-rate students can find employment. This tends to be a self-fulfilling prophecy; academic institutions pump poorly trained, badly motivated, and uncreative archaeologists into the CRM industry, leading to intellectual stultification and ethical lassitude that justify academics in their attitudes toward the field. There are ongoing arguments over who is "qualified" to conduct archaeological work under the heritage laws. Agencies like the National Park Service and organizations like the Register of Professional Archaeologists (http://rpanet.org/) promulgate and apply professional standards to resolve such arguments, but these are of little use as long as the academic community fails to produce graduates who appreciate and engage with CRM's intellectual challenges.

International Perspectives

It is probably safe to say that archaeologists in other countries – to the extent they consider the matter – view the US system with a degree of mild bemusement. Just as US archaeology differs from much of the world's archaeological practice by being mostly embedded in anthropology, so its legal management regime for archaeology differs from those of many nations by being integrated (sometimes uncomfortably) into the US environmental impact assessment and historic preservation systems. The non-centralized nature of these systems and the respect they accord (albeit

grudging) to private property rights also contrast with the legal systems of many other countries.

Because the USA has since World War II been a major player in the arena of international heritage preservation – usually represented by the federal agencies who dominate official US practice and are guided by US policy – there is some tendency to think of the US system as a model for other nations, but this may be ill-advised. The US laws governing archaeological resource management are the products of their own unique evolutionary trajectories and are not necessary relevant to the experiences, political structure, resources, or needs of other nations (c.f. King 2009, 2010).

Future Directions

Predicting the future is always a chancy affair, and doing so in a year like 2017 in the USA is particularly problematical. The political forces into whose control the 2016 general election delivered the US executive and legislative branches are openly hostile to the "administrative state" of which archaeology, as a part of CRM and environmental protection, has been a part since at least the late 1960s. The extent to which these forces will succeed in dismantling the administrative state remains to be seen, but it is virtually certain that they will cause the government officials responsible for CRM and environmental regulation to minimize their profiles. At the same time, their vigorous support for, and indeed identity with, extreme capitalism is likely to make the CRM and environmental impact assessment industries even more subservient than they have been to the forces of development. And the triumphal anti-intellectualism of the people now in control does not bode well for archaeology or any other thought-based pursuit.

However, it is arguable that the administrative state, including its environmental and CRM subunits, was overdue for reform. The very scale and complexity of the regulatory infrastructure – its laws, regulations, policies, programs, operating standards, and standard operations – are daunting to the citizen who tries to engage them, either to protect an important bit of the environment like an archaeological site or to advance what the citizen thinks to be a worthwhile project. It would have been nice to undertake this reform in an orderly, civilized manner, but even a devastating forest fire clears out the brush and allows new growth to shoot up. Some in the historic preservation community have begun thinking about new ways to do business (cf. Page and Miller 2016). It is just possible that when the current crisis has run its course – if we survive – it will be possible to build a new system that is more democratic, sustainable, and responsible to the broad public interest in archaeology, the environment, and human culture.

US National Park Service and World Heritage

Phyllis M. Ellin
Office of International Affairs, U.S. National Park Service, Washington, DC, USA

State of Knowledge and Current Debates

Introduction

In the United States, the Assistant Secretary of the Interior for Fish and Wildlife and Parks has responsibility for directing and coordinating participation in the World Heritage Convention. The National Park Service's Office of International Affairs provides technical staff support to the Assistant Secretary in this regard (Public Law 96–515; 54 U.S.C. 307,101; 36CFR73). This work includes coordinating preparation of US nominations to the World Heritage List (which are submitted through the US Department of State); maintaining and updating the US World Heritage Tentative List; submitting periodic reports on the condition of World Heritage sites in the United States to the World Heritage Centre of the United Nations Educational, Scientific and Cultural Organization (UNESCO); providing information and assistance to the public and to site representatives; and contributing to the US' positions on matters of World Heritage policy, in coordination with the State Department. The Office of International Affairs also forms part of the official US delegations to the annual meetings of the World Heritage Committee and other policy and technical meetings.

As of 2017, there are 23 World Heritage sites in the United States, 18 of which are also units of the

National Park System. Of the listed sites, several have significant archaeological components, including Cahokia Mounds State Historic Site in Illinois (inscribed on the World Heritage List in 1982), Chaco Culture in New Mexico (inscribed 1987), Mesa Verde National Park in Colorado (inscribed 1978), Papahānaumokuākea in Hawaii (inscribed 2010), and the Monumental Earthworks of Poverty Point (inscribed 2014).

The global significance for these sites is summarized by the UNESCO World Heritage Centre (http://whc.unesco.org/en/list/):

Cahokia Mounds State Historic Site: Cahokia Mounds, some 13 km north-east of St Louis, Missouri, is the largest pre-Columbian settlement north of Mexico. It was occupied primarily during the Mississippian period (800–1400), when it covered nearly 1600 ha and included some 120 mounds. It is a striking example of a complex chiefdom society, with many satellite mound centers and numerous outlying hamlets and villages. This agricultural society may have had a population of 10–20,000 at its peak between 1050 and 1150. Primary features at the site include Monks Mound, the largest prehistoric earthwork in the Americas, covering over 5 ha and standing 30 m high.

Chaco Culture: For over 2,000 years, Pueblo peoples occupied a vast region of the southwestern United States. Chaco Canyon, a major center of ancestral Pueblo culture between 850 and 1250, was a focus for ceremonials, trade, and political activity for the prehistoric Four Corners area. Chaco is remarkable for its monumental public and ceremonial buildings and its distinctive architecture – it has an ancient urban ceremonial center that is unlike anything constructed before or since. In addition to the Chaco Culture National Historical Park, the World Heritage property includes the Aztec Ruins National Monument and several smaller Chaco sites managed by the Bureau of Land Management.

Mesa Verde National Park: A great concentration of ancestral Pueblo Indian dwellings, built from the sixth to the twelfth century, can be found on the Mesa Verde plateau in southwest Colorado at an altitude of more than 2,600 m. Some 4,400 sites have been recorded, including villages built on the Mesa top. There are also imposing cliff dwellings, built of stone and comprising more than 100 rooms.

Papahānaumokuākea: Papahānaumokuākea is a vast and isolated linear cluster of small, low-lying islands and atolls, with their surrounding ocean, roughly 250 km to the northwest of the main Hawaiian Archipelago and extending over some 1931 km. The area has deep cosmological and traditional significance for living Native Hawaiian culture, as an ancestral environment, as an embodiment of the Hawaiian concept of kinship between people and the natural world, and as the place where it is believed that life originates and to where the spirits return after death. On two of the islands, Nihoa and Mokumanamana, there are archaeological remains relating to pre-European settlement and use. Much of the monument is made up of pelagic and deepwater habitats, with notable features such as seamounts and submerged banks, extensive coral reefs, and lagoons. It is one of the largest marine protected areas (MPAs) in the world.

Poverty Point: Monumental Earthworks of Poverty Point owes its name to a nineteenth-century plantation close to the site, which is in the Lower Mississippi Valley on a slightly elevated and narrow landform. The complex comprises five mounds, six concentric semielliptical ridges separated by shallow depressions, and a central plaza. It was created and used for residential and ceremonial purposes by a society of hunter fisher-gatherers between 3700 and 3100 BP. It is a remarkable achievement in earthen construction in North America that was unsurpassed for at least 2,000 years.

How US Nominations to the World Heritage List Are Made

US nominations to the World Heritage List are subject to certain prerequisites in the National Historic Preservation Act 1980 Amendments (Public Law 96–515; 54 U.S.C. 307,101). These require that any property nominated must have been previously determined to be of national significance to the United States, that there must be legal protections in place to ensure preservation of the property and its environment, and that the

owners of any non-Federal property must agree to the nomination. The requirement for owner consent has limited the types of properties that the United States can nominate: it is unlikely that large districts with many property owners, particularly in urban areas, could meet this requirement. Many such areas in other countries have been inscribed as World Heritage sites.

Archaeological properties are also included on the US World Heritage Tentative List. A Tentative List is a national list of properties that appear to meet the eligibility criteria for nomination to the World Heritage List. The World Heritage Committee's *Operational Guidelines* ask signatory nations to provide Tentative Lists to help evaluate properties for inscription. These annotated lists describe the sites that countries are likely to nominate in the next several years. In order to be nominated to the World Heritage List, a property must have been on its country's Tentative List for at least 1 year. Inclusion on the Tentative List does not confer any official status on a site; it means only that the site appears to meet the World Heritage criteria and may be nominated by the United States in the future.

The US Tentative List was most recently updated in 2016. It includes two sites that are primarily archaeological in nature: Hopewell Ceremonial Earthworks in Ohio, comprising Hopewell Culture National Historical Park, Newark Earthworks State Memorial and Fort Ancient State Memorial, and Serpent Mound in Ohio, an effigy mound. The Tentative List information on these properties can be found at http://whc.unesco.org/en/tentativelists/state=us.

The process for developing and submitting World Heritage nominations in the United States is established in Federal regulations (36CFR73). The regulations established the Federal Interagency Panel for World Heritage, which consists of eight Federal agencies that advise the Assistant Secretary on World Heritage matters, specifically the inclusion of sites on the Tentative List, the selection of sites for nomination from the Tentative List, and the evaluation of draft nomination dossiers for final submission. The Assistant Secretary is the chair of the Panel. In addition to the Assistant Secretary's office, the Panel comprises the Department of State, the National Park Service, the Fish and Wildlife Service, the National Oceanic and Atmospheric Administration, the Advisory Council on Historic Preservation, the President's Council on Environmental Quality, and the Smithsonian Institution. The regulations also establish requirements for public and official notification and public participation in the process.

The Office of International Affairs plays the primary technical role in shepherding potential nominations through this process. The staff provide representatives of sites on the Tentative List with information on the national and UNESCO program requirements and review draft materials based on a knowledge of how the World Heritage Committee and its technical Advisory Bodies have evaluated similar nominations. The preparation of the nomination dossier itself is the responsibility of the property owner. The Office of International Affairs draws on the expertise in natural and cultural resources of the rest of the National Park Service in this work, consulting with staff of the National Historic Landmarks Program, the Archeology Program, and other experts working throughout the country.

Historical Background

The United States was the first country to ratify the World Heritage Convention, in 1973. It also played a significant role in shaping the Convention as a vehicle to preserve both natural and cultural properties, as the National Park Service does in the United States. In promoting and entering into the Convention, the United States sought to apply these conservation ideals on a global scale, to benefit the most important places around the world. When the World Heritage Committee met in Washington, D.C. in 1978, the Committee included Yellowstone and Mesa Verde National Parks among the first World Heritage inscriptions.

The United States continued to make World Heritage nominations with regularity through the mid-1990s. Concern over the increasing size of the World Heritage List, which had become dominated by sites in Western and developed countries, as well as domestic controversy related to the inclusion of Yellowstone National Park on the

List of World Heritage in Danger in 1995, resulted in reduced activity related to World Heritage in the United States, and no nominations were made between 1994 and 2009. Following the creation of the 2008 US World Heritage Tentative List, the United States began to make nominations from it, successfully inscribing three additional sites, including Papahānaumokuākea and the Monumental Earthworks of Poverty Point.

The United States has served four terms on the 21-member World Heritage Committee, including a term as one of the original members. As part of the renewed World Heritage activity that resulted in the revised US Tentative List, the United States successfully ran for election to the Committee in 2005; that term concluded in 2009.

Current Issues

In 2008, the World Heritage Committee requested comments from countries signatory to the World Heritage Convention on the future of the Convention, in relation to its upcoming 40th anniversary in 2012. Comments submitted from a number of stakeholders expressed a desire to put more emphasis on the conservation of inscribed sites rather than the inscription of additional sites and noted a rapid increase in the number of World Heritage sites that taxes the capacity of the World Heritage Centre and the Committee. The politicization of many of the Committee's decisions has also been noted. However, the trends noted at that time have continued with little change to the present.

A significant issue for the US World Heritage program arises from the fact that the United States has been legally prohibited from paying dues to either UNESCO or the World Heritage Fund since 2011, when the member states that make up the General Assembly of UNESCO voted to include Palestine as a member of UNESCO. These laws (Pub. L. 101–246, title IV, Sec. 414, Feb. 16, 1990, 104 Stat. 70; and Pub. L. 103–236, title IV, Sec. 410, Apr. 30, 1994, 108 Stat. 454), dating from the 1990s, prohibit the United States from providing funds to any UN body that accepts Palestine as a member under the current circumstances. As a result, the United States has lost its vote in the UNESCO General Assembly and is disqualified from election to the World Heritage Committee. There is no current prohibition on making World Heritage nominations under these circumstances, but it is an unprecedented situation.

USA and Mexico (1970): Bilateral Treaties and Patrimonial Property Restitution

Miguel Angel Trinidad Melendez
Coordinación Nacional de Museos y Exposiciones, Instituto Nacional de Antropología e Historia, Teotihuacan, Estado de México, Mexico

Introduction

Increases in looting and illegal trafficking of ancient objects or monuments from countries with an important cultural heritage and a great compulsion for achieving pre-Columbian art

from Latin American countries with the objective of increasing private and museums' collections made specialists in cultural heritage, United Nations Educational, Scientific and Cultural Organization (UNESCO), and many countries to propose and establish rules for protect and preserve ancient cultural heritage.

Definition

In the last years of decade of 1960s, United Mexican States and the United States of America were working through diplomatic relations for considering establishing a compromise to protect each other's cultural heritage from trafficking with the goal to decrease illegal activities as looting and/or archaeological sites' destruction. In 1970, both countries signed a bilateral treaty for recovering and restitution of patrimonial properties.

Key Issues

Since 1930s, protection and conservation of cultural patrimony was focused by specialists and many countries which originally participate in *Athens Conference* (1931). Up to 1960s many steps on the way for protecting national heritage were done. By 1964, the General Conference of UNESCO, in its thirteenth session, adopts the *Recommendation on the Means of Prohibiting and Preventing the Illicit Import, Export, and Transfer of Ownership of Cultural Property* (Olivé Negrete and Cotton 2003: 106–110) asking the Member States to work with these statements on the way to adopt as soon as possible a Convention. It occurs at the General Conference in its sixteenth session on November 1970 (*Convention on the Means of Prohibiting and Preventing the Illicit Import, Export and Transfer of Ownership of Cultural Property*) (UNESCO 1970).

Based on *Declaration of Principles of International Cultural Co-operation* adopted by the General Conference of UNESCO on 1966, the IV Regional Conference of National Committees for UNESCO from West Hemisphere, on June 1967, in Mexico City, established the *Tlatelolco Resolution*. In this entry, the Conference suggested to Member States several measures should be taken to protect and promote cultural Latin American patrimony. Fifth suggestion is supported on the knowledge of increment on illicit trade of cultural items, and each state should ask UNESCO to promote an International Convention focused on prohibiting and avoiding illegal traffic and trade of art, movable objects, books, and documents (Olivé Negrete and Cotton 2003: 19–23).

As it happens in the entire world, looting and trafficking always are attached with other illegal activities and it is quite difficult to stop it by itself, especially because the free market for antiques from countries and extinct cultures with a great ancient heritage is not prohibited or ruled with laws based on respect, research, conservation, and diffusion of scientific and humanistic knowledge.

During the decades of 1960s, particularly in archaeological sites in West Coast, Maya lands, and Central Mexico (Teotihuacan), looters' activity and illegal trafficking increased due interest for achieving pre-Columbian art, historical objects, and documents. Many of them were stolen from archaeological sites, churches, and public files and libraries.

On the last years of this decade, diplomatic relations between Mexico and the USA were working on establishing bilateral rules to protect each other's cultural patrimony. In July 17, 1970, the *Treaty of Cooperation between the United Mexican States and the United States of America Providing for the Recovery and Return of Stolen Archaeological, Historical, and Cultural Properties* was signed.

In Mexico, this treaty, first, was approved by the Senate and ratified by presidency on November 1970 and then the exchange of ratifying legal instruments of both countries takes place on March 24, 1971, in Washington, D.C. Presidency wrote an ordinance on May 3, 1971, and then it was published to enter into force on *Official Journal of the Federation* on June 9, 1971 (Olivé Negrete and Cotton 2003: 175–178).

The main intention was based on a close cooperation and the desire for stimulating protection, study, and appreciation of goods with archaeological, historical, and cultural importance, and the resolution for promoting recovery and return of such properties.

Through several articles, both countries accorded to define the concepts, meanings, and the period in which properties were produce since pre-Columbian, historical, and modern times and including archives up to 1920.

They also took a compromise for stimulating research, to avoid illegal excavations in archaeological sites and stealing of archaeological, historical, or cultural properties. In the same sense, both parts will give facilities for movements and exhibitions on both countries of archaeological, historical, and cultural items with the intention of having mutual understanding and comprehension of artistic and cultural heritage of both parts.

Another important issue is the permission for legal international trade of art items, in accordance with legal statements that regards conservation of archaeological, historical, cultural, and national goods.

In this treaty, recovery and return will start with a request from one part, while the other accepts the compromise to apply all legal resources to recover and return goods that had been taken out from its original country after the date of the treaty's operative. Through diplomatic channels, the application part will give all documentation to establish the request. If it is not possible to recover and return by diplomatic media goods founded in its territory, authorities will promote a legal procedure to achieve this. In both countries, justice procurators are authorized to promote a legal procedure in its respective courts.

When the archaeological, historical, or cultural items will have the legal authorization for the return, all expenses will take charge by the requesting part. In this process, any person or part has the right for asking any reimbursement from the part which is returning the item. Finally, items will not cause any charge or penalty as a result of applying trade laws.

This is basically what the treaty is about and had been functioning since then for the benefit and protection of Mexico and US cultural heritage.

On November 1970, the *Convention on the Means of Prohibiting and Preventing the Illicit Import, Export and Transfer of Ownership of Cultural Property* was adopted by UNESCO and enters into force in 1972. Mexico accepted in the same year and USA until 1983 (UNESCO 1970).

Use of Cultural Heritage to Enhance Older People's Wellbeing

Laia Colomer[1,2] and Christen Lee Erlingsson[3]
[1]Department of Cultural Sciences, Linnaeus University, Kalmar, Sweden
[2]Department of Design, Linnaeus University, Kalmar, Sweden
[3]Department of Health and Caring Sciences, Linnaeus University, Kalmar, Sweden

Introduction

As life expectancy increases, many societies move towards a future in which a higher percentage of the population than ever before is older than 60 years. In the case of European Union countries, the number of older people in the population will almost double, rising from 85 million in 2008 to 151 million in 2060. The number of very old people (aged 80 years and above) is projected to increase by even more, almost tripling from 22 million in 2008 to 61 million in 2060 (European Commission 2009: 20–21 and 40). Moreover, senior lifestyles reflect a tendency towards a "long youth" rather than prolonged old age. The "Third Age" of active and healthy citizens age 60+ is being extended continuously, postponing the "Fourth Age" of older citizens in need of care, treatment, and rehabilitation. These trends, coupled with economic downturns and the likelihood of reduced future welfare benefits, will increase a relativization of retirement. This involves a departure from the existing life-course model of distinct, consecutive phases of education, work, and retirement/leisure to a more integrated model where education, work, and leisure increasingly take place throughout life (Walker and Maltby 2012).

Cultural heritage-based interactions can be utilized to stimulate life-long learning and to provide a focal point for older persons' reflections upon their lives and, and the meaning of cultural heritage for their wellbeing. The use of cultural heritage as a tool for supporting wellbeing, improved health, and quality of life among older people can benefit society as a whole, e.g., in relation to increased social cohesion, regional development, an enriched cultural environment, and intergenerational learning, while concurrently extending the knowledge base about the importance and roll of cultural heritage in supporting health. Around the world, the cultural heritage sector is embracing opportunities to support wellbeing, health and the quality of life for older people in an aging society and many older people already benefit from taking part in heritage activities (e.g., museum visits, genealogy, and local history research).

Definition

Wellbeing is a multifaceted and dynamic concept. It is described as a sense of how one's life is going, through the interaction between their circumstances, activities, and psychological resources. When achieving wellbeing, people gain a sense of individual vitality. This in turn facilitates undertaking activities that are meaningful, engaging, and which make them feel competent and autonomous. Wellbeing entails inner resources helping people to cope and be resilient. In a state of wellbeing, people feel a sense of relatedness to other people. In addition to personal, internally focused elements of wellbeing, social experiences, supportive relationships, and a sense of

connection with others is also enhanced (Michaelson et al. 2009: 8–9, 21). The use of cultural heritage as a tool for supporting wellbeing among older people draws in particular on active and creative engagements with the historic environment, folk traditions, archives, and archaeological/historical museums and collections.

Key Issues/Current Debates/Future Directions/Examples

Western societies are faced with the situation of increased life expectancy together with increasing numbers of older people outside the labor market. At the same time there is the decreasing number of young people contributing to the support of the older population. This relationship reflects profound challenges in modern population demographics, e.g., how to support high quality of life, processes of personal improvement and adaptation to change for older people. Another challenge is to obtain social cohesion, given that 40% of citizens age 65+ live alone and in risk of isolation. The changing demographic landscape also means increasing costs related to care. Thus, there is an economic interest for older people to belong to the Third Age group for a longer time and to the Fourth Age for a relatively shorter time. This entails developing methods and activities by which older people can maintain life quality and experience wellbeing. Therefore, in sync with the emerging trend of an aging population, there is an urgent interest to understand life quality, health, and wellbeing of older persons (Walker and Maltby 2012).

Cultural heritage can support people's health and wellbeing through stimulating memory and imagination, and experiences of beauty (Zipsane 2011; Ander et al. 2012). Cultural heritage can contribute to active aging and to development of novel care, treatment, and rehabilitation programs. Arts and craft activities had indicated positive therapeutic and medical outcomes, including reduction of stress, anxiety, depression, and blood pressure for the treatment and rehabilitation of all kinds of patients including older patients (Stuckey and Nobel 2010).

Cultural heritage activities aimed to support older people's wellbeing are based on varying approaches. One approach is activities based on life-long learning, for example, reminiscence activities that aim to trigger memories in participants experiencing and handling objects. Reminiscence sessions are also useful for older people who are socially isolated, allowing for social engagement with other participants (Osborn 1993). Participating older people report feeling happy and proud that both their personal memories are taken into social consideration and that others consider their professional and personal competences and skills as valuable.

In the case of older people in the Fourth Age or those suffering from dementia, their participation in museums and heritage programs that are focused on sensorially experiencing smells, sounds, touch, and sights influences changes in their emotions and leading to more positive mood, mental harmony, and lessened aggression (Zipsane 2011: 98). One example of this is an EU funded Erasmus+ project, "AHA-Active aging and heritage in adult learning" (Hansen 2017). Conducted at open air museums in five countries in Europe, the project is based on memory training visits by older people in the early stages of memory loss or dementia to venues recreating the atmosphere of the early 1940s. This project resulted in positive outcomes of these visits, for example, in stimulating memories and emotions, and increased wellbeing. Here it is understood that stimulating positive emotions facilitates the ability to think, plan, pursue training, and solve problems (Goleman 1995: 80, 85). Life-long learning is also supported by activities based on the idea that active aging enhances wellbeing. The Nordic Center of Heritage Learning (NCK) launched the Senior Citizens Heritage Learning Initiative that includes activities such as older people volunteering at museums and archives and participating in workshops, lectures, and special cultural heritage visits (Zipsane 2011).

A second approach focuses on non-pharmacological support to enhance wellbeing in older people receiving healthcare. The relation between handling museum objects and the promotion of health and wellbeing among hospital

inpatients and older people in residential care homes has been studied in the University College of London's "Heritage in Hospitals" project (Ander et al. 2012). Furthermore, handling museum collection objects has been shown to promote positive emotions, motivation, and interest in learning; relieve anxiety; and initiating personal memories in hospital patients. This results in bringing out a sense of vitality and energy overriding depressive feelings, providing renewed sense of identity (vs. institutionalization), stimulating social interaction, and enabling patients to find positive meaning in their current condition and lives. The outcomes of these museum-in-health interventions are statistically significant improvements on measures of wellbeing and happiness (Ander et al. 2012: 6–7; see also Chatterjee and Noble 2013). Following these results, the UCL team has developed both a protocol for museum objects handling sessions (Ander et al. 2012), and a museum's wellbeing measures toolkit (Thompson and Chatterjee 2014). Essentially, the "Heritage in Hospitals" studies are part of a general public health strategy in seeking to understand the value of nonpharmacological approaches such as heritage-based activities for health and wellbeing. This reflects the long-standing interest among cultural heritage professionals for making museums and galleries more responsive to the society they serve, beyond the already ongoing education and social cohesion programs.

The inclusion of wellbeing perspectives into museums', galleries', and heritage places' planning and goals could not only foster increased quality of life for older people (and possibly lower public costs for caretaking) but could also have the outcome of creating a win-win situation for the cultural heritage sector in general. Reminiscence activities in heritage places and museums, listening to patients' stories and experiences while handling collection objects, and open curatorial participative practices are defining museum's venues and objects with new meaning and value. For example, the "Re-Active" project in open air museums reported that reminiscence activities were found to be especially valuable and that engaging in cultural heritage activities fosters community's involvement (see Hansen 2014). Furthermore, museum object-handling interventions in hospitals and loaning out memory boxes for care homes and day centers give museum's collections further uses extending beyond storage, exhibition, and programs for school children.

In conclusion, it is interesting to recall that politicians and policy makers have been promoting cultural access for all citizens, signifying that culture and cultural heritage play a role in enhancing older peoples' wellbeing, and that museums and other heritage institutions should provide learning activities particularly for older people. Indeed, more national and international funding is being granted to projects aimed to stimulate research and programs focusing on supporting wellbeing among older people (e.g., EU's Framework Program for Research and Innovation Horizon 2020). There are also a growing number of researchers who argue that politicians and public officers should stop viewing culture as a low productivity branch of the economy mainly absorbing resources, and realize that the cultural sector is actually saving public investments through increasing social cohesion and inclusion through programs in the areas of migration, public healthcare and general welfare (e.g., Sacco 2013). Guided by the current demographic scenario, policy insights, and market context, Hansen and Zipsane (2014) suggest also that the heritage sector should acknowledge older people as a potential market for cultural heritage institutions, offering activities and experiences that are designed in collaboration with older people to be specifically interesting and appealing to this group.

Future Directions

Supporting wellbeing among older people opens new curatorial and management opportunities and challenges in applied cultural heritage. Wellbeing can provide a broad conceptual framework for evaluating the role of cultural heritage in the lives of older people, both on individual and community levels. Prospective outcomes of heritage activities can also benefit society as a whole, e.g.,

in relation to social cohesion, regional development, intergenerational learning, and provide a rich cultural environment while extending our knowledge base about older peoples' experiences and desires concerning heritage. Last but not least, there is the potential of reduced costs of care and rehabilitation if wellbeing and life quality are supported in the older population.

As seen in the short review above, current research on connections between cultural heritage, aging, and wellbeing among older people indicates that cultural heritage has an important role in supporting wellbeing among older people. But much remains to be investigated in this innovative research area. For example, research is needed in the currently very relevant area of migration that focuses on older people with migrant backgrounds, i.e., with "different" personal memories from those collected and represented in national, regional, and local museums. Many migrant populations are large and diverse in composition in Western societies after WWII. These new citizens are growing older and reaching retirement age in their countries of adoption. In the resulting multicultural scenario, immigrant identity is a combination of memories and experiences from both their cultural landscape of origin and from the host country, a mix of everything that has relevance in creating a particular bi-cultural sense of belonging (Colomer 2013). Therefore, activities and approaches such as reminiscence, museum loan boxes, object handling, and various activities designed specifically for the wellbeing of "native" older citizens would need to be studied and re-evaluated to be properly adapted to include older citizens with migrant backgrounds.

In summary, this innovative area of supporting older people's wellbeing at the interface of cultural heritage, museums, and health and social services is exciting, expanding, and highly topical. Future research is needed that focuses specifically on the opportunities and risks of cultural heritage as a tool for improved wellbeing and quality of life among older people, drawing in particular on active and creative engagements with the historic environment, folk traditions, archives, and archaeological/historical museums and collections. This will also extend pedagogical and didactic knowledge by focusing on how older people reflect upon lifelong learning.

Uses of Heritage

Laurajane Smith
School of Archaeology and Anthropology, Australian National University, Canberra, ACT, Australia

Introduction

Published in 2006 by Routledge, the book *Uses of Heritage* offers a re-theorization of heritage that de-privileges the idea of heritage as a "thing," place, or site. It develops two interlinked arguments, the first of which is that heritage is a performance of meaning making and second these performances are framed by different discourses about heritage. The most conspicuous discourse is what the book terms the "Authorized Heritage Discourse," or AHD. In de-privileging the idea of heritage as material, as a "thing," the book draws on the work of the historian Raphael Samuel (1994), and explores the idea that heritage "things" are "theaters of memory," where the past and present are negotiated through the performances of heritage management, preservation, and visiting. Heritage is a process of remembering and meaning making, in which understandings of both the past and present are continually negotiated by the performance of identifying, managing, and visiting heritage places or participating in heritage events which are social and therefore intangible. All heritage is thus intangible, because heritage is what happens at and around heritage places or events – perhaps organized around a place, artifact, or site, though it may be an intangible event such as a ceremony or artistic performance; it is a moment of action, not a thing or place itself. While the sites, artifacts, and places may be important, they are important only in terms of how they facilitate or are used as cultural tools in the cultural and social "work" that heritage does in society.

Key Issues

The book finds synergy with the arguments by Dicks (2000, 2007), Harvey (2001), and Kirshenblatt-Gimblett (1998) that respectively stress heritage is a form of communicative practice, a verb, and a practice of cultural production. It also has synergy with Sharon Macdonald's (2013) arguments about "past-presenting." Debates from within the social sciences about memory and remembering, sense of place, emotion and affect, dissonance, identity, and performance are drawn on to develop a nuanced picture of heritage as a process ultimately concerned with the regulation of social and cultural change and conflict. It challenges the idea that heritage is ultimately "good," "comfortable," monolithic, and universally valuable and argues that ultimately all heritage is fundamentally dissonant and contested.

The contested nature of heritage and the role it plays in the arbitration and regulation of social and political conflict are often obscured by the AHD. This dominant discourse is embedded in the policies and legal frameworks utilized to manage and conserve heritage (or cultural resources), which were developed in many Western countries during the nineteenth and twentieth centuries, and is embedded in intergovernmental agencies such as UNESCO and ICOMOS. This is not to say that there is a single AHD or that such discourses are immutable or beyond challenge; however, within many Western countries and intergovernmental agencies, there is a core of shared understandings about the nature of heritage. These commonalities of understanding have their origin in Western Europe in the nineteenth century and the lobbying of archaeologists and architects for the protection of the material culture that they deemed to be of innate and inheritable value (see chapters 1–3).

Critical discourse analysis (CDA) underpins the conceptualization of the AHD. As such, discourse is defined as being both reflective of and constitutive of social practices, as it is "a practice not just of representing the world, but of signifying the world, constituting and constructing the world in meaning" (Fairclough 1992: 64). This means that discourse not only helps define and frame the way we may think, talk, and write about the world but that a particular discourse will also arbitrate and frame our practices.

The AHD defines heritage as "fragile, finite, and nonrenewable" and as something that must be preserved for future generations. Under the AHD, heritage tends to be defined as aesthetically pleasing and nationally significant material objects, sites, places, or landscapes that represent all that is "good" or worthy of celebration from the past. The value of material culture is assumed to be innate rather than associative or attributed. As something fragile and finite, those possessing appropriate expertise are privileged within this discourse over other stakeholders (such as economic interests, local or other communities, or social or political interest groups), and experts are defined as the "stewards for the past," who have a professional "duty" to safeguard heritage and to communicate the value of heritage to nonexperts.

The AHD also stresses the idea of inheritance; heritage, under the guidance of experts, must be passed onto the future, if not untouched, at least unchanged. Thus, people in the present are dissuaded from actively rewriting the meaning of the past or reconsidering its role in the present. These basic tenets derive from European architectural conservation debates, particularly John Ruskin and William Morris' idea of "conserve as found." Heritage is thus defined as something that is "found" rather than made or conceptualized, and its fabric is understood as inherently meaningful and historically and culturally valuable. The idea that the meaning and value of heritage sites may change, that it may be disputed both over time and within particular contexts, and that ultimately a site is simply a collection of bits and pieces that someone or various groups have attached meaning and value to becomes an uncomfortable perception. My assertion in the book, for instance, that Stonehenge is merely "a collection of rocks in a field" (p. 3), has met with some disbelief and ire (for instance, Soli 2011) from those with an emotional and intellectual investment in the framework of the AHD. However, Stonehenge, like other heritage sites, has acquired new and disparate meanings over time.

Its "finding" relates to the way it is conceived, and it has been refound over the centuries and redefined as an archaeological site, tourist attraction, site of druidic worship, and observatory, among other understandings – and at one time (by the then owner of the land it is on) as an inconvenient collection of rocks in a field.

The degree of importance that is placed on the materiality in Western culture, alongside assumptions about the aesthetic worth of certain objects or sites made within the AHD, means that the material artifact or site has often come to be seen as embodying the social or cultural values that have been attached to it. Thus, a monument or heritage site tends to become confused with the cultural and social values that are used to interpret it and give it meaning. For instance, Stonehenge becomes something that "just is" of significance. This process tends to obscure the possibility that heritage may not only have multiple meanings or values for different people or social groups but that some of these values may conflict or contradict each other. Further, it disavows the possibility that some groups may not value a site or place at all. The AHD places emphasis on the national and universal value of heritage and tends to de-privilege local value, community value, or other values that a place of heritage may have to subnational groups or interests. Certainly, a hierarchy of value is defined and maintained within the AHD.

Assumptions about the innate value of heritage also work to reinforce the idea that heritage represents all that is good and important about the past. This assumption also links to a key construction within the AHD that heritage and identity are irrevocably linked. Not only do heritage sites come to stand in for the values used to give them meaning, they also tend to be seen as standing in for "identity," particularly national identity. Exactly how heritage and identity (and the concept of identity tends to be seen as self-evident within the discourse) are linked is never articulated or defined – again it is a given that "just is."

The AHD constructs not only a particular definition of heritage but also an authorized mentality and framework that guides and regulates heritage preservation practices and public policy developments in many Western countries. While the specifics of the AHD will vary across time and space, these core concepts have currency and consequences not only for heritage experts but also for all those communities, individuals, and other interests or groups who engage with and regard heritage (however they may define it) as important. The consequences of the AHD are that it tends to regulate and confine professional and academic debate about the nature and meaning of heritage and the way it can be managed, preserved, and interpreted. This means that it also tends to validate the bodies of knowledge and values that contributed to it – it is by definition self-referential. It also excludes those understandings of heritage that may sit outside of the framework defined by the AHD. The AHD tends to be embedded in Western and more particularly international policy, an occurrence that gives authority or authorization and legitimacy to the discourse and the assumptions embedded within it within the West. Although the AHD has been challenged to some degree by increasing international interest in intangible heritage, there is much within the Western AHD that escapes criticism in this development (see chapter 3 and Smith and Waterton 2009a; Smith 2015; Smith and Campbell 2017).

In developing my arguments about the AHD, and the idea of heritage as a cultural performance rather than a "thing," the book presents several case studies, drawn primarily from England and Australia, which illustrate the performative nature of heritage and the social and cultural negotiations that are undertaken as part of this performance. These case studies in the first instance look at how the AHD influences engagements with heritage sites. Interviews with visitors to English country houses and an ethnographic study of the Riversleigh World Heritage site in Australia are used to explore the way the AHD constructs certain social and cultural meanings and the consequences this has for underpinning power relations between different social and cultural groups. Three case studies also examine definitions of heritage that sit outside of, or in opposition to, the AHD. Visitor interviews with people at museums of working-class life; an ethnographic analysis of the development of a community

heritage organization in the deindustrialized town of Castleford, West Yorkshire; and a review of Australian and US Indigenous debates and conflicts over heritage provide examples of heritage discourses that seek to challenge the AHD. The challenges documented in these case studies illustrate the degree to which heritage becomes an important resource in the politics of identity. To understand this process, the work of Nancy Fraser on the "politics of recognition" is drawn on, to illustrate that heritage is not only ultimately political but how it may be actively taken up in political struggles. Fraser (1995) argues that in the latter twentieth century, "identity politics" became an important form of political struggle for those seeking social justice. The recognition of the special and specific claims that particular groups made for the redistribution of resources of power (such as welfare, education, housing, and so forth) was often underpinned by appeals or reference to particular understandings of history and culture (Fraser 2001). The recognition of difference has thus become an important aspect of political conflicts, and heritage is often used to legitimize claims to identity, and as such it has become a key resource in these struggles. These insights, which began to be developed in the last sections of *Uses of Heritage*, have since been developed further (see Smith 2007, 2010, 2017; Smith and Waterton 2009b, 2011).

Uses of Heritage has largely met with positive critical attention. For Ian Baxter (2007: 130), the book was identified as being "seminal" in the emerging debates within heritage studies about "power, accord, and dissonance." Others have noted that, while the AHD may be an "annoying acronym" or sounds like a disease, it provides a useful and compelling heuristic devise for exploring the consequences of heritage practices (Feintuch 2007; Warren-Findley 2007: 149). The book has also been praised for, unlike all too much writing on heritage, offering detailed analysis of interview and other ethnographic data to support its arguments (Feintuch 2007; Warren-Findley 2007; Dicks 2007; Day 2009). Others, particularly those heavily invested in the AHD, have been less convinced and note that I "failed to consider the scientific issues entailed in managing resources" (James 2007: 788). The de-privileging of expertise (or science) in the hopes of developing more democratic heritage practices and understandings has been a long-term issue underlying my work with heritage (see Smith 1994), and while this has and continues to receive criticism (for instance, Soli 2011; Carman 2011), it is not a position I back away from. Indeed, engaging with how different communities connect with heritage, and understanding that scientific expertise is simply one of many communities of interest in heritage (Smith and Waterton 2009b: 19), is vital if academic and professional debate is to grow and develop. As Baxter (2007: 128) notes, heritage studies is an emerging field of enquiry that will only reach maturity with the development of debates that aim to question and reexplore the established canon. I actually think that the sort of ultra-defensive claims made by James (2007) goes some way to demonstrating the validity of my arguments.

A common mischaracterization of my work is that it is based on a social constructivist epistemology (see, e.g., Albert 2013: 11; Harrison 2015: 27) and that I thus adopt a relativist ontology. This mischaracterization tends to be linked to a discomfort with my de-privileging of materiality (see, e.g., Harrison 2013). Rather than taking a relativist or constructivist position, my work is firmly based within critical realism, an ontological philosophical position that also underpins CDA (2006: 13–16). *Uses of Heritage* does not dismiss the importance of "things"; indeed I argue they are useful and important cultural tools for the processes and performances of heritage making. Rather the book points to the overprivileging of materiality in dominant discourses and practices and argues that we need to broaden our conceptualization of heritage to engage with a wider range of experiences of heritage and heritage making than have been traditionally acknowledged and authorized.

Some have taken issue with my reading of critical realism, arguing that the ideas that heritage is a performative process (that all heritage is intangible) are an epistemic fallacy within

critical realism (Skrede and Hølleland 2018: 83). This critique simply misunderstands that critical realism does not discount that the social and social structures are "real" and have material consequences in people's lives. Skrede and Hølleland (2018) are also concerned that I have not done a detailed critical discourse analysis to demonstrate the AHD, and they are correct in this; a detailed analysis is not done within *Uses of Heritage,* but this was not the aim of the book. I drew on the broad ideas of critical discourse studies that underline CDA to acknowledge the existence of a dominant discourse so that it may be challenged. My mistake was referring only to CDA, which is a methodology, rather than more clearly pulling out the basic ideas underpinning a critical approach to the idea of discourse on which my arguments were based. Contra to the assumption made by Skrede and Hølleland (2018: 86) that establishing the AHD was the central concern of the book and that examining alternative discourses was not, my aim was rather to open the conceptual space for alternative discourses, and, indeed, the second half of the book illustrates the range of alternative and competing discourses to the AHD.

The arguments in *Uses of Heritage* have, as Iain Robertson points out (2012), been widely taken up within the heritage literature (see, for instance, essays in Graham and Howard 2008; Gibson and Pendlebury 2009; Harrison 2010; West 2010; Benton 2010; Skrede and Hølleland 2018). While I have developed aspects of the work further, particularly in a 4-year research project funded by the Australian Research Council, which has allowed me to extend the research on visitor responses to heritage to Australia and the USA, others have started to extend the debate. Emma Waterton (2010), for instance, has documented in more detail the nature of the AHD in England and within UNESCO and the way it has responded to policy attempts focusing on "social inclusion." The concept of the AHD has begun to take on a life of its own and not only within academic and professional debate. A Google search for the term revealed it being used in a mountain bike discussion list based in the UK. The discussion was about finding new places to go bike riding in, and someone suggested that the group should contact the Scottish National Trust to find places, with the reply from a member of the group that national trusts were:

> . . .organisations for people that need their heritage spoon fed. Not real heritage either, heritage chosen by white, middle class, self-appointed experts, presenting their own values and narratives of the great and good as though they are appropriate to us all and form what we all view as the national treasures. It's called the AHD, the authorised heritage discourse. (Trailmonkey 2010)

As an author, I find it very gratifying that the book has made an impact in academic discussions of heritage. However, many practitioners and policymakers have told me that the book, and the concept of the AHD in particular, speaks very directly to their experiences of the heritage sector. To actually find a trail bike discussion list citing the AHD shows that the concept works for some people, and a glance through Google also shows that beyond academic use there is also a growing take-up of the ideas and terminology of the book in heritage policy documents, which is very encouraging.

I would like to finish however by highlighting an element of the work that has not been explored as much as I would like. That is the emphasis the book places on resistance to hegemonic discourses and in particular the sections on working-class heritage. What these sections show (and see Smith, Shackel and Campbell 2011 and the *International Journal of Heritage Studies* 17(4) for further developments of these arguments) is that we do not need to go to non-Western locations to find alternative or oppositional heritage narratives or experiences. What the sections of the book on working-class heritage show is that the country house style of heritage experience, though dominating many people's sense of what heritage is or may be, does not sit well with everyone's understanding of heritage. The emphasis on performance, intangible manifestations of heritage, dissonance, and community found in many non-Western contexts can also be

found in the backyard, so to speak, of Western heritage researchers and policymakers. Hopefully, this will change, and more people will explore this aspect of the book.

Utopian Communities, Archaeology of

Velasquez S. H. Verónica
Instituto de Ciencias Sociales y Humanidades, Área Académica de Historia y Antropología, Universidad Autónoma del Estado de Hidalgo, Pachuca, Hidalgo, Mexico
Department of Archaeology, University of Sheffield, Sheffield, UK

Introduction

The study of utopian communities is a research field that has been mainly the endeavor of historians and anthropologists. However, archaeologists have focused their attention to the research of these peculiar kinds of settlements and their material culture. Utopian communities are found in many geographical regions that include Europe and the American continent. These social experiments emerged as a response to the Industrial Revolution and capitalism and were inspired by the ideas of French, English, and American thinkers. A large number of utopian communities were founded in the United States, and towards 1860, around 130 secular- and religious-oriented communities existed that included Fourierist, Mormon, Shaker, Icarian, and Perfectionist ones, Hutterites, Rappites, and Zoarites, and Saint Simonians (Hayden 1981; Holloway 1966). There exist a variety of examples of archaeological research and theoretical approaches on these types of settlements (Kozakavich 2017) and range from eighteenth-century colonization projects in Patagonia, Argentina (Senatore 2007) to nineteenth and twentieth-century religious and secular communities in North America and in Mexico (Velasquez 2012). Moreover, research on utopias from Historical Archaeology has shed light on burial practices amongst the Quakers in Alexandria (Bromberg and Shephard 2006), the relationship between the ideological realm and the practice of everyday life (see Van Bueren 2006), gender (Spencer-Wood 1991, 2006), consumption patterns, and material culture that reveal the lifestyles and values of particular societies (see Kozakavich 2006; Starbuck 2004; Van Wormer and Timothy Gross 2006; Van Wormer 2006), and architectural projects (see Preucel and Pendery 2006; Tarlow 2002; Tomaso et al. 2006).

Definition

The archaeology of utopia can be defined as a field that studies counter-cultural communities. That is, communities that live at the margins of a dominant ideological and economic system like capitalism, and set forth a series the practices that include alternative modes of production and the organization of religious and social life. These communities were created following two basic principles that are: dissatisfaction with aspects of the dominant culture and the belief that a better way of life is possible (Van Bueren and Tarlow 2006). Thomas More coined the term *utopia* in 1516 to refer to a place that does not exist; the term *utopia*, on the other hand, has been employed to encompass the projects of real visionaries who seek alternative lifestyles (Kozakavich 2017; Van Bueren and Tarlow 2006). It is also a secular heaven, a model society in America created by those who flew from the industrial problems in Europe. These model societies or social experiments aimed to provide examples which they hoped the world would follow (Holloway 1966). Not all groups of people who chose to separate themselves from the broader society were utopian; to be considered as such, the group must act according to the Western utopian literary and philosophical tradition and can be rather radical in their goals and ideals. Therefore, the term utopia applies better to some groups more than others and can be best understood as an *intention* and an activating impulse that informs and inspires people to create or achieve an ideal society (Kozakavich 2017). These can also be defined as intentional communities, a concept that encompasses groups with a variety of philosophical principles and religious beliefs, family structures, and economic forms. Intentional communities have planned residential groupings, shared economic, religious, and social values, and the intention to live alternative life-styles (Kozakavich 2017).

The members of utopia aimed to construct a perfect society according with their religious, or political ideals, and their leaders sought to set an example for the rest of the world. These communitarian experiments followed particular religious or secular philosophies, and could congregate a dozen or hundreds of persons through which ideal societies were established. The members of utopia have made a conscious decision to live differently and separately from the rest of society. The communities are visionary and missionary and believe to represent the best future for humanity. They are highly designed and communally organized (Tarlow 2002). Utopian settlements are relatively small in size and located at a certain distance from major population centers, are self-contained, and in some cases, religion constitutes the main element in their conformation (Orser 2002: 556–557).

Key Issues/Current Debates/Future Directions/Examples

Gender

Archaeological research on gender has the potential to inform on the accuracy of the idealistic drawings of utopian settlements and features that were predominantly used by women. These include degree of cooperative housekeeping, the transformation of culture and of women's roles, and the adoption and/or refusal of artifacts invented by the communards (Spencer-Wood 2006). Research on the materialistic domestic reforms that took place during the nineteenth century in the Boston area, for example, suggests changes in the construction of gender (Spencer-Wood 1991). Materialistic domestic reformers sought to make women dominant in the domestic sphere, transform gender ideology, and improve women's status, lives, and work. Their purpose was to professionalize women's occupations and empower them by applying scientific, industrial, and business principles and introducing innovations in the material culture used in housework. These included the latest scientific technology, which could provide efficient house designs and housekeeping machinery that would decrease the amount of work required by housework. These innovations were controlled, and sometimes even developed, by women, and sympathetic men. The reformers believed that women's work should have the same status as men's skilled work and used technological innovation to transform housework into a public profession; housework was extended and professionalized into the public realm. This resulted in cooperatives where women from different families participated in large-scale production processes in the public sphere. Cooperatives transformed unpaid housework into remunerative skilled labor in the public sphere, such as kitchens, laundries, and day cares. These drew on the beliefs of the community as a family and the scientific efficiency of collective labor developed by communitarian socialists like Fourier and Owen, amongst others. Some of these cooperative housekeeping facilities and equipment were incorporated into utopian communities, such as the Shakers, Rappite Harmony Society Towns, Owenite communes, Fourierist Associations, Brook Farm, Oneida Perfectionists, Amana Inspirationist communes, and Hutterites. Despite their varying religious backgrounds, utopian communities often developed similar public cooperative housekeeping organizations that included cooperative laundries, kitchens, and schools. Because in the nineteenth century most communes subscribed to the egalitarianism philosophical principles of the Enlightenment, they considered all work equal, although women continued to perform cooperative domestic work. Members of utopias made housework the equivalent of other kinds of public labor and sought improvements in facilities and furniture that would increase the efficiency of domestic work, such as large spaces for communal food preparation, laundry, cleaning, and childcare. Also, improvements to sanitary and lighting facilities, such as those used by the Oneida Community, sought to maximize members' health and decrease domestic labor. Shaker domestic innovations included a washing machine, a cheese press, and a flat broom, amongst others. The Oneida Perfectionists developed methods for fruit preservation and created an improved mop wringer and an institutional potato peeler (Spencer-Wood

1991). Overall, the research on these communities and the materialistic domestic reforms yield information on the construction of gender ideology and roles through the innovation and use of material culture. They professionalized housework and changed women's status and labor, empowering women by redefining the domestic sphere as overlapping with the public one, as women worked outside their home and the public space was domesticated. Moreover, the research on these communities shows women's resistance to male dominance in both the private and public spheres and how notions of gender changed in these cultural systems (Spencer-Wood 1991).

Architecture

The modification and reinterpretation of the landscape, and the design of architectural projects were central to utopian communities. While many of these were actually constructed, and are valuable sources for archaeological interpretation on the life inside utopia, others were never materialized. This has been explored at sites like Floridablanca and Brook Farm, and in the Crédit Foncier Company, where the ideal city of Peace remained as a future project (see below). Most utopian thinkers envisioned themselves as social architects and thought that they could transform society through architectural designs, and some embodied eccentric ideas. Many intended to re-structure a complete city and country. Some projects emerged as a response to the Industrial Revolution and adopted symbols linked with gardens and agriculture, or with the machinery and industry, and incorporated them to the physical layout. The physical plan intended to fuse their ideals on nature, family, and society. Behind every utopia, there is a complex and well-structured plan on the physical layout of the communities because the physical spaces condition social behavior. Even when the designs vary from one utopia to another, in general terms they have areas for communal activities and others intended for private or family living. The architectural layout is crucial to the study of utopia because by analyzing it, it is possible to understand the social and ideological mechanisms that operated inside the community (Hayden 1981). These culturally built landscapes had the intention of molding its inhabitants' behavior to suit ideological and religious goals, as observed in Shaker communities, and these landscapes were not static; they moved and were modified in response to internal changes and the community's needs (Kozakavich 2017).

Llano del Rio Cooperative, was established by Job Harriman near Los Angeles in the mid-1910s, as an alternative to the dehumanizing forces of industrial capitalism. Harriman created plans for a model city that was intended to create a self-sufficient, egalitarian, and secular community. Spaces within this socialist cooperative were influenced by progressive agendas, domestic reforms, and women. These spaces highlighted the ideals held by members of the utopia stressing beauty, solidarity, and equality of opportunities as well the importance of labor-saving devices that would liberate women from domestic tasks (Van Bueren 2006).

In Feltville, New Jersey, a small-scale industrial village dedicated to paper-making, bookbinding, and printing was designed and operated by David Felt, a liberal Unitarian printer and stationer, from 1845 to 1860. Data drawn from historical geography and archaeological finds suggest that the values built in Feltville were those of a secular but Christian, capitalist, and classist community, and that the daily segregation and prevailing social order and hierarchies were inscribed into the village's landscape (Tomaso et al. 2006).

Floridablanca was created as part of the Spanish peopling project of the Patagonia coast, Argentina, and was a small colony that was inhabited between 1780 and 1784. Located near the port of Saint Julian in the province of Santa Cruz this colonization project was inspired by the ideas derived from the Enlightenment. It was part of a defensive strategy to protect this geographical region from English colonizers and that involved the peopling of this territory with Spanish families. The social project was innovative for that time in that it selected impoverished families and bachelors dedicated to agriculture and that knew useful crafts and domestic activities. Neither foreigners nor people with illnesses were generally

admitted. A contract was signed between the Crown and the colonists that obliged them to settle in Patagonia and could not abandon the region without prior authorization. The research project aimed to understand the creation, reproduction, and transformation of the discourses derived from the Spanish Enlightenment underlying the colonization project, as well as the social practices of the settlers. An interesting result of the archaeological project conducted at Floridablanca was obtained from the analysis of the architectural layout of the site. The households of the colonizers were found to be homogenous in size and design and other buildings did not adjust to the official architectural project. The first was interpreted as the material representation of the ideal of equality of the Enlightenment, but the others that were constructed by the settlers were not mentioned in the official representations and narratives of the settlement, as they did not adjust to the ideal layout (Senatore 2007).

Brook Farm was one of the most famous utopian communities in North America. Located in Roxbury, Massachusetts, it was founded during the nineteenth century by George and Sophia Ripley and functioned from 1841 to 1847. Despite the fact that the occupation of the site ranges from the pre-Historic period to the twentieth century, it is best known for its utopian component. The archaeological research at this site focused on the materiality of the cultural landscape, on the built environment of the utopian community. It aimed to understand the social practices by which philosophies such as Transcendentalism and Fourierism were successfully inscribed in the architecture and settlement patterns of the community (Preucel and Pendery 2006). This allowed insights to the daily lives of the community members and explore the reasons behind the adoption of Fourierism. The results obtained from the research at Brook Farm suggested that Transcendentalism was a philosophy that promoted egalitarianism and this view was embedded in the landscape through the moral elevation of agriculture. Moreover, an egalitarian program inside the community of volunteer labor was observed in the unplanned expansion of the settlement and the use of eclectic architecture that emphasized individualism. In contrast, the adoption of Fourierism promoted a more authoritarian system that aimed to control every aspect of social life and that included sexual behavior. This philosophy was materialized in the form of a phalanstery, and the centralization of activities in that building, an expansion of the industry, and the standardization of communal architecture (Preucel and Pendery 2006).

Consumption of Material Culture

Utopian communities are alternative projects to capitalism. Therefore, the analysis of consumption of material culture recovered at these sites allows to explore the relationship between communal ideals and the material world, the interaction with the dominant culture and economic system to which they oppose (Orser 2002; Tarlow 2002). In this regard, resistance actions within utopian settlements can be translated into technological innovations that are typical of this kind of communities (Leone 1999). Also, a higher consumption of locally manufactured goods in contrast to others produced by the dominant system is expected. But, the analysis of the material culture from utopia often reveals contradictions between the social and religious ideals and everyday practice and consumption.

The research done at the religious Shaker community of Canterbury, New Hampshire, that functioned from 1783 until 1992 included an assessment of the built environment and the mapping of the surface of the village. It combined a mixed approach that included archaeological work, documentary research, interviews, cataloguing, and the elaboration of inventories. The results of the excavations revealed material culture like clay tobacco pipes and items manufactured in the outside world like alcohol and perfume bottles, ceramics, and little material culture that was actually manufactured by members of the community (Starbuck 2004).

Another example of how Archaeology can unveil contradictions underlying utopia is provided by the research done on Russian *doukhobors*. These groups fled from the tsarist regime to

Canada during the late nineteenth century in search of new territories. The community originated as a reform movement against the Russian Orthodox Church during the eighteenth century. It was characterized by a belief in a divine ray that inhabited every living being and thus, believed in the equality of life. The members of this society practiced communalism, pacifism, and vegetarianism. Smoking and drinking was prohibited. The material culture recovered comprised bottles of wine, whiskey, gin, and beer. Also, remains of beef, poultry, rabbit, and fish were identified. Regarding communalism, the ceramic sample suggested that rather than communal dining there existed inequality in the patterns of consumption of material culture between one dwelling and another (Little 2007). The research undertaken by Kozakavich (2006) at the site of the former *doukhobor* village of Kirilovka, located on the south bank of the North Saskatchewan River valley, near the town of Langham, started as a cultural resource management project. The excavations at the village site and the artifacts recovered, particularly liquor bottles, further support the idea that drinking was practiced in village life. The analyses of a variety of faunal remains suggest an abandonment of vegetarianism, finding evidence of the consumption of beef, poultry, rabbit, and fish, and possible pork and sheep. Moreover, the material culture found at Kirilovka does not support the maintenance of true communalism at a village level. Also, the identification of a variety of ceramic vessels with different decorative patterns, indicative of individual purchases of pieces instead of whole table sets, suggests that family dining behavior incorporated purchased mass-produced tableware. Differences found in the artifacts recovered from the eastern and the western sides of the village, such as purchased toys, watches, glass, and improvements to the household, are suggestive of differential consumer patterns and activities that were probably motivated by different interpretations and practice of Doukhoborism on the part of the residents. The research shows that Doukhobor identity was dynamic and subject to change through time and that their material choices expressed how ethnicity, ideology, and economics shaped people's practices and daily life (Kozakavich 2006).

The Crédit Foncier Company was established in 1866 in the valley of El Fuerte in Sinaloa, Mexico. Its founder, Albert K. Owen, was inspired by Quaker ideas and utopian thinkers like Robert Owen and Charles Fourier. He envisioned the bay of Topolobampo as the place where to construct Pacific City. Like most utopias, Owen carefully selected its members, whom were mainly devoted to agricultural activities, architects, shoemakers, horticulturists, editors, and topographers, amongst others. The rules inside the colony were strict and discouraged the consumption of alcohol and tobacco. Although it was never constructed, the layout of the city and buildings suggest a physical separation between the community and the outside world, and promoted communal interaction. Followers of Owen migrated to Mexico from Europe and the United States to join the project and settled along the valley, where they lived in nuclear families, constructed houses, and devoted to agricultural activities. Owen published a periodical pamphlet with images of the colony in order to promote it and attract new adepts. These photographs provide insights to the mechanisms of ethnogenesis and self-presentation of the colony, as a heaven on earth surrounded by gardens, livestock, abundant resources, communal activities, and family houses. This would probably provide the outside world with an image of being self-sufficient. However, this was contradicted by the material culture recovered at the sites and the documentary sources in the form of personal letters of members of the community that narrate a life of stress, poverty, and illness (Velasquez 2012). Although there was evidence of technological innovation in the shape of a sugar mill and chimney, the finding of imported ceramics and bottles suggests that the colonists were barely self-sufficient and relied upon the envoys from abroad. Moreover, alcohol bottles were also identified in the analyzed samples (Velasquez 2012).

The archaeological research of utopia enables to explore the social dynamics inside the

communities. Also, how its members constructed a self-image and their interpretation of the world they inhabit. It provides insights to the contradictions underlying the relationship between the ideological realm and the materiality of everyday life. The contradictions found in the patterns of consumption for example, illustrate the strategies set forth by members of utopia in order to survive. It could be argued that in every utopia, there existed an imaginary or ideal one, and the material one that left traces in the archaeological record. And, it is the job of archaeologists to explore how these conciliated with one another and what can they say about the transformation of the world and the construction of alternative narratives. It is important to understand that the incongruities found inside utopian communities involve a continuous praxis of reinvention, construction, deconstruction, and reconstruction of an ideal world. Utopia is not static but rather dynamic and constantly changing and adapting to new output. This contradicts the utopian ideal of constructing a perfect, permanent, and static community. As it has been observed in the cases presented above, utopia seldom stays at the margins of the world they oppose. Future directions should focus on the experience of manhood and womanhood to assess notions on equality. Also, it is important to address the attitudes towards the body in terms of architectural designs, clothing, hygiene, sexual and food abstinence as the embodiment of particular ideologies. Because most studies have focused on nineteenth-century settlements in North America, and utopia arises as a counter-culture that opposes the dominant social, economic, and ideological system, it is necessary to broaden the field to other periods and geographical areas. These could comprise from medieval communities, to runaway slave settlements, and millenarist and new age projects that put into practice resistance, alternative ways of life, redemption, and salvation. One of the most substantial contributions made by Archaeology to the study of utopia is to provide an alternative narrative to the official one. Through the study of material culture, that is seldom documented, it is possible to venture to the life within these communities and explore the social dynamics inside them.

Introduction

The 75-km-long Valcamonica (Camonica Valley) in the Italian Alps includes over 300,000 rock engravings spanning 10,000 years, from the Epipaleolithic period to the Middle Ages. The valley is at the crossing of the Alps from Italy to Central Europe where both ideas and people passed through. Since 1956 this area has been studied for 60 years by the same team, enabling scholars to explore the meaning of stylistic and thematic changes from period to period. After defining the essential archeological elements of chronology, economy, and cultural identities, the main efforts were oriented toward the conceptual analysis of behavioral patterns, religious beliefs, and the meaning of the rock art depictions. Changes in the way of thinking, in the economy, and in the social organization contribute to our understanding of the formative period of the European society.

Thanks to the research results, Valcamonica was declared by UNESCO as "World Cultural Heritage" in 1979. It was the first rock art site in the world to obtain such nomination and the first Italian site to become part of the World Heritage list. Valcamonica is also renowned for the new research approach applied, focusing on the use of rock art as a means of historical reconstruction, producing history for periods considered as prehistoric.

The succession of different styles of rock art allows the definition of a sequence of Camunian periods illustrating 10,000 years of events and human adventures. The numerous cases of superimpositions, the depictions of datable weapons, tools, and objects and the presence of extinct animals in the earliest phases and of datable inscriptions in the later ones make this sequence a chronological pillar of post-Paleolithic rock art in Europe.

The proto-Camunian period dates back to the end of the Pleistocene and the first phases of the Holocene, 12,000–7500 years ago. The final post-Camunian period documents the "historic" phases: Roman, Medieval, and recent.

In each period, rock art reflects the interests and concerns of its time, the economy, the beliefs and the cult, the social organization, the political trends, and the international relations. In certain periods, tools and weapons illustrate foreign objects or foreign influence. The introduction of

new technology such as the wheel or metalworking or weaving is meaningful for defining the way of life. Changes in the economic activities; in religious and worship habits; in the architecture of huts, of shrines, and of other buildings depicted in the rock art; in different funerary practices; and in other descriptions of habits provide the historical background of the various periods, each having its specific stylistic, typological, and thematic character.

Key Issues/Current Debates/Future Directions/Examples

Proto-Camunian Period (12,000–5500 BCE)

In the pre-Boreal and Boreal climatic stages, this rock art relates to pre-Neolithic culture. Pollen analysis from geological logging in Valcamonica shows this period's tall trees were pine trees and birches. Material culture is characterized by a lithic industry of blades and abundant microliths. The iconographic style is defined as a simplified naturalism with figures schematized just by a contour line. Main themes are large animals represented in large, almost natural size. Sometimes their images are shown to be hit by spears. Elk figures are exclusive to this period and are not found in later periods. In this area this animal became extinct during the early Holocene. Human figures are absent. Weapons and tools are limited to spears or darts. The essential economic activities are hunting and fishing.

There are stylistic and thematic similarities with the rock art of the Arctic region and archaic hunter phases in the Near East and North Africa. Analogous expressions are known elsewhere in Italy in Levanzo (Egadi) and the cave of Addaura, Monte Pellegrino (Sicily). There are similarities with the archaic rock art of Austria and Portugal and, with some instances, of rock paintings in Levantine Spain.

In Europe, this style developed in the late phases of the Upper Paleolithic earlier than 10,000 years ago. Such rock art is typical of hunter-gatherers of the terminal Paleolithic and the Epipaleolithic periods.

Camunian Periods I–II (5500–3300 BCE)

In this period, style changes drastically, and the repertory reveals a social revolution. The main subject matter is stylized anthropomorphic figures mostly with upraised hands. The sharp changes in subject matter and style reveal a new population in Valcamonica practicing a complex economy, which included agriculture and animal rearing. Large groups of human figures illustrate assembly and socializing. The previous artists were dependent on their prey which was the focus of their interest and likely of their cognitive concepts. In the new economy, man becomes the focus, and there is awareness in society and socialization reflecting the importance of team cooperation and the need of conviviality. People were organized in larger social units requiring coordination and planning. Hunter-gatherers became food producers, and the social structure was more complex, more sophisticated, and also more problematic. In the late phases of Period II, large ghostlike anthropomorphic figures appear, some of them being over 2 m high. This suggests an ideology concerning humanlike supernatural beings. Figures of anthropomorphic spirits are present in Central and Eastern Europe since the beginning of the sixth millennium BCE.

The Camunian Periods I and II correspond to the Neolithic of the fertile plains. During the Climatic Optimum, Valcamonica was a rocky land but had forests of firs, alders, oaks, and some grassland that fostered animal grazing.

The material culture is Neolithic with pottery which is characteristic of cultures generally present in Northern Italy, the so-called Bocca Quadrata (square mouth pots) and that of the Lagozza Culture. This rock art represents figures of axes and other tools used in the same period. It includes also the earliest figures of plows.

Period I includes adoration symbols, such as the solar disc or the axe. In the subsequent period (Period II), there are also representations of rituals and social and economic gatherings. Some scenes represent ceremonial occasions. Cult activities appear to have been diversified and probably occupied a relevant place in daily life.

Period I and II weapons and tools are spears, boomerangs, bows and arrows, paddles, and hoes and plows. The first domesticated animals appear (dogs, oxen, and then goats). Sun worshipping and worshipping the dead are added to at the end of Period II with the evidence of animal (especially dog) worshipping.

Neolithic objects excavated from the shelter Riparo Gaban are decorated with repeated ideograms and an anthropomorphic figure similar to the "spirits" of Valcamonica.

The Late Neolithic of Central Europe was a period of international contacts, trade gradually developed, and ethnic entities were aware of the deeds and customs of other human groups. While the Camunian tribes were producing rock engravings, the first urban civilizations were emerging in the Near East.

Toward the end of Period II, the first anthropomorphic images on standing stones or menhir-statues appear. Such images will then occupy a dominant role in the rock art of Valcamonica in the successive Period III-A. These monuments consist in engraved or painted anthropomorphic stones. Often they are boulders, reaching up to over two meters in length, selected by man for their peculiar, vaguely anthropomorphic, natural shape. These stone monuments reflect a new element in the iconography and thus in the ideology at Valcamonica from around 3350 BCE. Similar monuments appear earlier in various parts of Europe and Asia throughout the Neolithic period. They reveal the presence of a widespread religious movement that interested various areas of Eurasia. It reached the Alpine area with some delay, in respect to other regions. Here it acquired specific local patterns reflecting new ideological trends.

Camunian Period III-A (3,350–2500 BCE)

Period III has been divided into two sizable stages, III-A and III-B-C-D. Their art illustrates an interesting conceptual development in cultures, beliefs, and social organizations. Period III-A corresponds to the Chalcolithic period, in the early sub-Boreal climatic stage, and marks the beginning of metallurgy in the area.

Several monumental compositions and menhir-statues represent a tripartite concept of the world. Solar and/or lunar images are the head of an anthropomorphized world; the central part of the body includes the breast and necklaces for feminine figures or weapons for masculine figures; the lower part is either a pubic triangle, a snake, or two weapons positioned as the legs of vaguely anthropomorphic beings. The concept of a tripartite universe appears in the menhir-statues of the fourth millennium BCE in the Alps, in Valcamonica, and in Valtellina.

The meaning of these cosmological images that can be male, female, or having an undefined gender still requires an explanation. What is the ideology behind the images? How does the idea developed? The concept of a tripartite universe and of a tripartite human society will later become a main core of Indo-European ideology.

The tripartite menhir-statues appear at the same time as the earliest depictions of wheels, daggers, and other metal weapons. Metallurgy was not invented but imported and probably arrived with a new ideology, which was assimilated and reshaped.

Depictions of weapons and tools are numerous and represent metal daggers, axes, spears, and halberds of the same typology as archeological findings in Northern Italy and Central Europe in this period. Wheeled wagons indicate a new age for communication and transportation.

Domesticated animals include dogs, oxen, goats, and now pigs. The technological and cultural innovations are illustrated by the rock art. The plow, the wheeled vehicles, weapons and tools made of metal reveal the essential economic activities, including animal breeding, agriculture and hunting, complementing metalwork, organized trade, and professional craftsmanship.

The rock art compositions of this period are among the most elegant, best-planned, and suggestive works of the whole Camunian cycle. Engraved rock surfaces and menhir-statues are concentrated in cult sites, open-air sanctuaries where tens of such monuments are found in single areas, and the presence of fireplaces near the menhir-statues, heaps of stones, and other stone structures indicate a wide range of performances

and cult activities. The sanctuaries are likely to have occupied an important role of gathering, socialization, and ritualization of events.

As the places of worship grow in number, priesthood is arguably acquiring a dominant role, a privileged class in a regime that looks like an oligarchic-theocratic system.

Toward the end of the Chalcolithic period and the beginning of the Bronze Age, around 2500 BCE, a new change takes place in the style of rock art. The symbols represented on monumental compositions spread to the entire rock. The daggers and the axes change typology: they are no longer Chalcolithic; they are Early Bronze Age. The focus of interest is no more the tripartite entity. Single figures that were part of the monumental composition and of the iconography of the menhir-statues in the Chalcolithic period are now represented and probably worshipped individually. An iconographic development is illustrated by strange compositions of weapons, which together make a sort of anthropomorphic being. The tripartite universal giant is replaced by mythical beings having weapons and tools as limbs. A new age introduces new idols.

Camunian Periods III-B-C-D (2,500–1200 BCE)

In Period III-B-C-D, changes in the themes and style herald changes in the social system. Modes of depiction change, and in each phase, figures of tools and weapons contribute to establish a well-documented chronology. The standard Bronze Age chronology of the region lasts from 2500 to 1200 BCE. Period III-B belongs to the Early Bronze Age; Period III-C relates to the end of the Early and the beginning of the Middle Bronze Age, while Period III-D covers the later phases of the Middle and the beginning of the Late Bronze Age. The transition between the Bronze Age and the Iron Age is tentatively dated in this Alpine area to c. 800 BCE.

From phase to phase, the rock art is changing the focus on themes, changing its typology (grammar), and the kind of compositions and association of signs and figures (syntax). Changes in grammar and syntax reflect changes in the concerns and the way of thinking of the makers and reveal the conceptual dynamics of a restless Bronze Age.

Besides the wealth of weapons and other objects, the iconography includes compositions considered to represent fields and other territorial features. In the second millennium BCE, they are among the earliest known "topographic maps."

Toward the end of this period, mythological scenes and anthropomorphic figures in action bring a new stylistic approach to the rock art. The change is drastic and anticipates the character of the rock art in the Iron Age. The most common weapons are subtriangular daggers, battle-axes, spears, and shields. The chronological definition of the numerous depictions of metal weapons and tools is supported by comparable finds in datable archaeological excavations.

Dogs, oxen, goats, and pigs continue to be present among the domesticated animals with the additional appearance of the horse, which soon occupies an important place in the iconography of the Iron Age. Technological and cultural innovations represented in rock art suggest an increase in metalwork and weaving. Hunting, fishing, agriculture, and animal breeding continue, but new economic dynamics develop as a consequence of trade and the accumulation of surplus. The growth in the region of hillforts or "castellieri" indicates the political and social context of the changes recorded by the rock art typology.

Another change is recorded after the described evolution of beliefs and religion. The rock art shows that the trinity vision of the universe, the cosmological religion of the Chalcolithic, gradually turned into a cult of objects and weapons. Apparently the conceptual emphasis moved from the cult of the "Purusha-like" universal creator to the cult and worship of weapons and to the magic power of metal tools.

Period III, at different moments, shows parallels with the rock art of Mount Bego (France), with that of Southern Scandinavia, and of the Iberian Peninsula. Some areas of Europe have rock art styles and themes evolving in similar orientations, indicating the presence of similar trends over rather vast regions.

Camunian Period IV (1200–16 BCE)

The end of the Bronze Age and the transition to the Iron Age brought new cultural winds. In the Mediterranean regions, dynamic political structures developed with thriving city-states. Seafaring promoted trades. The hillforts in Valcamonica and other neighbor valleys illustrate the development of local chiefdoms. In the Alpine regions, introverted tribes gradually opened up to international relations. The trade of amber and precious metals used transalpine tracks, and the mountain regions acquired benefits from these exchanges. Metal ores were exploited and metal tools were traded. Wagons and weapons of Mycenaean type are represented in the rock art of Valcamonica. Figures of wheeled wagons are figured in the rock art, funerary structures, and other monuments through Germany, all the way north to Scandinavia.

The Camunian Period IV coincides with the later phases of the Bronze Age, the Final Bronze Age, and the Iron Age. Five main typological phases are recognized, the first two in the Bronze Age and the three other in the Iron Age. Climatically, it starts with a relatively hot climate that gradually becomes colder and more humid; this is the end of the sub-Boreal stage and most of the sub-Atlantic.

The character of the iconographic style has become realistic, narrative with descriptive and anecdotal scenes of daily life, of magic, and of mythological nature. Figures of isolated tools and weapons are typical of the Bronze Age and tend to become rare in the Iron Age. The magic power of the mythic tools is transmitted to the magic power of mythic heroes. In the Iron Age, weapons and tools are mostly represented, held by people. They include shields, helmets, swords, lances, and axes. Many agricultural instruments are represented in scenes showing people using them: plows, hoes, sickles, and picks. There are numerous figures of structures, huts, barns, shrines, and temples. Representations of handicraft activities include plowing of agricultural land, metalwork, and the construction of wheels and the making of wheeled wagons and of architectural building.

Domesticated animals are more diversified than in the Bronze Age: dogs, oxen, horses, donkeys, goats, ducks, chickens, and geese. The breeding of rabbits appears at later stages. During this period, writing begins using a local language in the Northern Etruscan alphabet. Essential economic activities are trading, mineral extraction, metalwork, animal breeding, agriculture, and hunting. The categories of professional warriors and priests emerge. In the initial phases, the sociopolitical structure is based on the lordships of the hillforts (castellieri). Later, the depictions of groups of warriors and the growing number of fighting scenes present the image of an unstable and warlike society.

Beliefs and religion are drastically changed toward the end of the Bronze Age. When compared to previous periods, conceptual innovations are considerable. Rock figures often represent epical and heroic events likely to have similar inspirations to those of the Germanic mythology.

In the Final Bronze Age, thematic and stylistic analogies with bronze and pottery decorations of the Urnfield and proto-Villanovan cultures are evident. In the Early Iron Age, the middle phases of Period IV, there are strong Villanovan and Etruscan influences. In the late phases, Celtic, Rhaetian, and Venetian influences alternate each other in less than three centuries. International relations and cultural influences appear to move dynamically. Something happened with the traditional beliefs. New ideas were colonizing the Alpine Camunians. Images of imported gods gradually replaced those of ancestors and mythic heroes.

The last phases of rock art, preceding the arrival of the Roman legions in 16 BCE, display a decadent style. The low quality of the shapes of the rock engravings is in apparent contrast with the introduction of secondary details in the representation of objects like shields, hats, or musical instruments. Figures acquire signs of new stylistic trends due to external influence. The Camunians were conquered by the culture of Rome even before the arrival of the Roman Legions.

The custom of producing rock art as a pattern of culture came to its conclusion with the Roman occupation. In the last 2000 years, since the full introduction of theistic religions, sporadic rock

engravings were made, in Roman, Medieval, and recent times, but the rock art was no longer a cultural and ritual necessity.

Conclusions

The rock art of Valcamonica is an archive of 10,000 years of European history. Over 300,000 pictures mirror the events that shaped the evolution of European society, from hunter-gatherers to a more modern way of life. This immense art body has been documented, recorded, and described. It must now be understood. The ancient Camunians did not produce their pictorial "database" just to embellish the rock surfaces. Rock art was used as a means of communicating messages, commemorating events, teaching the candidates to initiation, operating magic, and other purposes. They tell stories that we have to understand. Research is progressing toward decoding the pictures engraved on the rock surfaces. This is the present challenge of research: producing history out of an archive of depictions left behind by prehistoric peoples.

van der Merwe, Nikolaas J.

David Killick
University of Arizona, Tucson, AZ, USA

Basic Biographical Information

Nikolaas Johannes van der Merwe was born in South Africa in 1940. In 1958, he won a scholarship (offered by a Trans Atlantic shipping line) to attend Yale University, from which he graduated in 1962 with a B.S. in Physics. Yale was then very active in the development of archaeological sciences, and under the joint supervision of the archaeologist Kwang-chi Chang, the radiocarbon scientist Minze Stuiver, and the geochemist Karl Turekian, he investigated for his doctoral dissertation the feasibility of dating iron-carbon alloys (steel and cast iron) by radiocarbon. He received his Ph.D. in Anthropology from Yale in 1966. He was an Assistant, then Associate Professor in the Department of Anthropology of the State University of New York at Binghamton from 1966 to 1974. In 1974, he was appointed as the first Professor of Archaeology at the University of Cape Town in South Africa. In 1988, he returned to the USA as the first Landon T. Clay Professor of Archaeological Sciences at Harvard University, a position he held until 2001, when he was appointed as University Professor of Natural Sciences at the University of Cape Town. He retired in 2005 to Kalk Bay, near Cape Town. Among the honors bestowed upon him are the 1994 John F. Herschel Medal for Interdisciplinary Research (Royal Society of South Africa) and the 1998 Pomerance Medal for Scientific Contributions to Archaeology (Archaeological Institute of America).

Major Accomplishments

Nik van der Merwe is best known for pioneering the use of stable carbon isotopes to infer past diet from the analysis of body tissues. This has been hailed as "one of the great triumphs of scientific archaeology" (Pollard et al. 2007: 183). It is

probably the only scientific approach developed within archaeology that has been widely adopted in other fields of science and now provides an extremely important set of tools for biogeochemistry, zoology, ecology, nutrition, and food sciences. By 1970, van der Merwe was aware that radiocarbon laboratories had identified systematic offsets between radiocarbon dates on wood charcoal and on some types of carbonized annual plants. The latter were almost all tropical grasses, a group that includes the major cultigens maize, sorghum, and African millets. He realized that this provided the means to track the spread of maize agriculture through North America. Working in South Africa with the radiocarbon scientist John Vogel, he measured and plotted the stable carbon isotope ratios of human bone collagen in samples spanning the first millennium CE in eastern North America and showed that maize did not become a major cultigen until after 800 CE. Publication of these results was delayed for several years by negative reviews from archaeologists, who insisted that this date was far too late, but their eventual appearance (Vogel and van der Merwe 1977; van der Merwe and Vogel 1978) forced a major reevaluation of the later prehistory of eastern North America. He subsequently tracked the spread of maize into highland Peru and the South American rain forest (e.g., van der Merwe et al. 1981) and with his student Julia Lee-Thorp pioneered the isotopic investigation of early hominid diets from the carbon in tooth enamel (van der Merwe et al. 2003). He has published many studies outside archaeology and is hailed as one of the founders of the field of isotopic ecology.

Although his doctoral dissertation research (van der Merwe 1969) had shown that iron-carbon alloys could be directly dated, the technique was little used because of the large sample size required. The development of AMS radiocarbon dating from the late 1980s allowed the dating of much smaller samples, a development of great potential value for archaeometallurgy (e.g., Cook et al. 2003). His doctoral work also required technical proficiency in archaeometallurgy. He directed a major archaeological survey and excavation project between 1970 and 1974 on prehistoric copper- and ironworking around Phalaborwa in north-eastern South Africa, undertook ethnoarchaeological studies of ironworking in Malawi, and contributed several important syntheses of research on the origins and spread of metallurgy through Africa (e.g., Miller and van der Merwe 1994).

He was largely responsible for introducing African archaeologists to archaeological science, and the doctoral students that he trained at the University of Cape Town have greatly expanded the range of the research that he initiated. These include Julia Lee-Thorp (Oxford) and Francis Thackeray (South African Museums) on isotopes and human evolution, Judy Sealy (Cape Town) on hunter-gatherer and pastoralist diets in southern Africa, David Killick (Arizona) on archaeometallurgy, and Anne Cohen (Woods Hole Oceanographic Institute) on marine isotope ecology. The isotope laboratory that he founded at the University of Cape Town remains at the forefront of research in light stable isotope ecology.

He also played an important role behind the scenes in advising the post-apartheid government of South Africa on the restructuring of universities and particularly on the continuing importance of university-based research. It is probably no coincidence that funding for archaeological research has been maintained at a high level in South Africa, in marked contrast to the woeful state of funding for archaeology in most other nations in sub-Saharan Africa.

Van Project

Douglass Bailey
Department of Anthropology, San Francisco State University, San Francisco, CA, USA

Introduction

In July 2006, a team led by Cassie Newland and John Schofield excavated a 1991 Mk 3 Ford Transit van and posed the critical question: what does it mean to do archaeology? One of the seminal projects in an archaeology of the contemporary and recent past, the Van Project followed orthodox archaeological methodology, recording, analysis, and interpretation and challenged core assumptions about the discipline, its objects of study, and the role of archaeology within contemporary society.

Key Issues/Current Debates/Future Directions/Examples

The Ironbridge Museum (Telford, UK) had used the van from 1991 to 2005, first for the museum's archaeological unit and then for its works and maintenance teams. Van excavation strategy was standard, followed the Museum of London's Archaeological Site Manual, and started with library, archive, and oral research. Next, the interior of the van was gridded in 20 cm units, and a first layer of the site was divided into two contexts: the carpets and mats in the front of the van (context 1,059) and the carpets and wooden floor in the back (1,001). Details of importance were drawn to scale and photographed; elevations were drawn at a scale of 1:10 and plans at 1:10 or 1:20. Once these contexts had been recorded and artifacts photographed in situ, objects were collected. A second layer (the metal floor of the van) was then identified and defined by three more contexts: the offside of the cab (1,037), the nearside of the cab (1,039), and the back of the van (1,024). These contexts were recorded and artifacts collected. The five contexts yielded 352 cultural artifacts that were bagged and tagged with context numbers. In addition, each context was sampled for forensic, chemical, environmental, and entomological analyses. Features of the van's chassis were given context numbers, were photographed or drawn, and were examined for evidence of usewear. Following surface recording and artifact collection, the van chassis and engine were dismantled; individual components were assessed, measured, photographed, and planned on site. Finds and records were archived at Ironbridge; the carcass of the van was recycled at a scrapyard.

Based on Adrian Myer's finds analysis, the majority of artifacts were associated with the archaeological or the maintenance phase of van use. Analysis identified two main artifact categories: mass-produced vehicle components and van parts and deposited artifacts. The latter included historic materials (i.e., ceramics) from the van's use by the Ironbridge archaeologists, objects associated with electricians and their work, and miscellaneous or misplaced objects unassociated with

either of the vehicle's two formal use-phases. Further analysis included a detailed typology for screws (and a cache of 36 brass, slotted-drive, flat-head screws) and the standard attributions of categories of use (e.g., wood working, electrics). Further subclassification of electrical artifacts was based on frequency: domestic maintenance artifacts were most common, followed by fuse and bulbs, followed by high voltage and industrial materials. Examination of material associated with Ironbridge archaeological activity identified and dated a ceramic pipe stem, ceramic sherds dating from 120 CE through the nineteenth century, early twentieth-century glass fragments, building daub, and slag from a blast furnace. Other finds were less easily categorized: liquids were classified as multi-stratified and were handled as deposit samples. A final category of objects, nonwork artifacts, included plastic and foil candy wrappers, plastic coffee stirrers, cigarette butts, a fruit stone (*Prunus domestica* ssp. Domestica), an adhesive sticker from an apple, the detritus from tobacco consumption, metallic confetti, decorations and miscellanea from holiday celebrations, and other ephemeral activities not connected to orally documented uses of the vehicle.

Post-excavation analysis included mapping the spatial distributions of artifacts across van strata and contexts, as well as sourcing materials used in the construction of the van and in the artifacts excavated from it. Analysis of environmental samples (by Steve Davis) revealed 60 taxa of beetles (represented by 119 individuals) including woodworm (*Anobium punctatum*) and other woodland taxa and synanthropic taxa (e.g., *Oryzaephilus surinamensis*) which are common in urban contexts associated with stored cereals and seeds, and beetles of the Lathridiidae family which are commonly found in mold or plant debris. This environmental assemblage represents an infestation of the van itself and is not related directly to the vehicle's use.

Forensic analysis (carried out by Anna Nilsson) included fingerprinting (to establish patterns in van use) and hair analysis (to characterize van occupants). The unequal location and concentration of fingerprints suggest frequent driving of the van by a series of different individuals often traveling without a front seat passenger. Human and animal hair was recovered: the latter from a cat (*Felis catus*) and a dog (*Canis domesticus*) and the former long and bleached or dyed, perhaps identifying a woman's presence.

Identification of vehicle function suggests a use for transportation of tools and archaeological finds but also of the supplies and detritus of maintenance crews, as well as for other unexpected, non-sanctioned uses: traveling to celebrations and parties, transport of a personal pet (the museum did not utilize guard dogs), or other mundane activities (snacking and smoking).

Analysis of use-wear on the body of the van suggested a history of misuse and multiauthored reworkings of the vehicle which created a vehicle significantly displaced from its original design and which may best be understood in unique terms of the van's own particular biography. The excavators concluded that the "van-envion emerged through dwelling and eating, resting and sheltering; as lunch-table and lunch; workplace and playground, being site, situation and folk-memory" and thus should be understood in terms of a dwelling perspective (*sensu* Ingold).

At an epistemological level, the Van Project made important contributions to a modern, critical archaeology, to its practice, its objects of study, and its relevance to contemporary society. For the practice of archaeology, the project demonstrated that not every artifact fits easily into the documented phases or functions determined for a site (e.g., the celebratory artifacts, such as the confetti, which oral testimony suggested were deposited during non-sanctioned use of the van). Also, the project showed clearly how a single artifact will have many different uses and users, meanings, and interpretations, each of which must be acknowledged as equally authoritative in any interpretation. Furthermore, the project provided clear evidence of how the condition of one component of an artifact or site (e.g., the van's engine) may have been affected by (re)workings that another component (the van's body) may not have experienced; thus, sites and artifacts can be disjoint and internally heterogeneous. Finally,

artifact analysis demonstrated that some artifacts and traces of past activity will not fit into regular categorization (e.g., the liquids from the van engine, the confetti, the dog hair) and will provide vital unexpected information about otherwise unrecorded, ephemeral behavior and activity.

At a more reflexive level, the project demonstrated that meaning derives not only from an artifact's uses and positions in the past but also from the archaeological actions practiced upon it. Excavation (as well as preservation or interpretation) informs on the people and activities of a site's life history, on the perceptual biases of traditional archaeology, and on the explanatory breadth and refinement of thought that accompanies a study of modern material culture. Thus, the archaeological record that was created as the van excavation proceeded was continuously turned back into the process of excavation, layering new factual strata onto the metal, wood, and artifactual sedimentations of the site.

In addition, the project demonstrated that the most insightful archaeological investigations are multivocal and give equal attention to the opinions and commentary of popular sources as to academic experts. Van Project output ranged from traditional academic articles in *Cambridge Journal of Archaeology* (Bailey et al. 2009) and the *International Journal of Historical Archaeology* (Myers 2011) to more ephemeral, public output: interactive blogs, daily progress reports on the excavation, audio and video diaries, Internet message boards, short films, news reports, public discussions, and opinion gathering. Wide, public debate was enabled and provoked; a "collision of responses" was anticipated and accommodated. Output was live, dynamic, and open, inviting response and critique that were fed into ongoing excavation and interpretation.

On a more general level, the project illustrated the detail and breadth of information that can be obtained from a study of the common and the mundane. It showed how an archaeology of the contemporary or recent past can transform familiar objects into unfamiliar ones and, in doing so, provide original perspectives that open new understandings of what is taken for granted in the modern industrialized world. Critically, the project opened the horizons of archaeology to a world of experience and material far beyond the limits of the ancient past and thus destroyed the traditional boundaries that separate archaeology from modern material culture studies and popular history.

The project showed that the study of modern material culture requires a direct and targeted approach that interrogates the complexities and multiple nuances of a single object. As well as provoking these discussions of discipline, methodology, and epistemology, the Van Project retained its own scientific currency; it was more than mere provocation or intellectual exercise. The project was an independent and self-contained research study of the material culture of mass production in late twentieth century. The archaeological interrogation of contemporary material culture is a powerful means for studying patterns of human behavior and perceptions. Projects such as the van excavation are particularly valuable when practiced in an industrialized modern world of objects that is so vast and plentiful that overarching syntheses are, if not impossible to carry out, of little value beyond their over generalizing conclusions.

While the project can be viewed as a completed, self-contained work, the impact of the van lives on. After the remains of the completely excavated van were sent to a recycling facility, the stripped down ferrous metals were exported to Turkey to be made into construction materials that now form parts of modern buildings. Other metals, such as aluminum, were sent to East Asia; brass, bronze, and lead went to China; and plastic, foam, and fabric went into local UK landfills, continuing a never-ending material and archaeological voyage. The archaeology of the van (just like the materials of the van and the knowledge and debate created by it) continues beyond the limit of the project; comment, teaching, inspiration, and clone projects roll on.

Vandalism and Looting (Ethics)

Ioanna Antoniadou
Independent Scholar, Thessaloniki, Greece

Introduction

In the examination of "vandalism" and "looting," emphasis is placed upon the agency and – by implication – the ethical standpoint from which these terms are asserted, used, theorized, and, as phenomena, treated. This entry begins therefore with the professionalized archaeological standpoint, which dominantly views looting as a form of destruction that is instigated and maintained by the demand of the antiquities' market and the vast availability of economically motivated nonprofessional diggers unearthing cultural objects on a global scale. The impact of war/conflict upon vandalism and looting is a topic examined later, as it draws special attention upon the underlying ideological factors which maintain and encourage these phenomena, besides the economic crisis entailed. It also creates unique ramifications in terms of the extent and nature of the looting/vandalism phenomena. A brief account follows on the legal discourse that is adopted, as well as the technology that is used in the attempt to intercept the development of vandalism/looting. In the end, alternative approaches are presented, as they encourage a unique conceptualization and deconstruction of the vandalism/looting phenomena while they illustrate their historical and sociopolitical contexts and throw light upon the looters' motives and perspectives.

Definition

Vandalism and looting are dominantly defined as two interconnected phenomena that entail a wide spectrum of practices, ranging from the unscientific extraction of antiquities out of undisturbed ground to the formation of unprovenanced antiquities' collections. Divergence in the discourse surrounding these terms lies not so much in the account of the actions or processes involved but in the ethical and ideological standpoint from which they are approached, theorized, and labeled. Professionalized archaeological views that espouse preservationist values discuss the vandalism and looting of cultural heritage in connection with their assumed self-interested and/or profit-related motives, the violation of archaeological ethics, the consequent physical damage, as well as the discursive impairment regarding the insight into the past. Concurrently, post-processual archaeological and anthropological approaches that advocate multi-stakeholder values regard these phenomena as diverse acts of nonprofessional disturbance of the material past and throw light upon the historical, social, economic, and ideological contexts that surround them, as well as encourage the consideration of their unique forms, motivations, purposes, and implications developing on the ground.

Looting in Archaeological Contexts

Unregulated disturbance of the material past is as old as the awareness of the past (Schnapp 1996). The urgency to define, distinguish, and establish the appropriate and authorized behavior toward ancient remains arose with the rendering of their significance and the notion of their protection in the context of rising nationalisms in Europe, in light of the implications that ancient remains had in the formation and preservation of national

identities (Anderson 1991; Hamilakis 2007). As archaeological discourse was developing in its own terms, it was also being defined on the basis of its contrast from long-held practices that, from that point onward, started to be conceived as unscientific, unethical, unprofessional, or illegal. Across the scope of physical interactions with the past, the ideology and practice of a professionalized archaeology distinguished itself from categories such as collecting and antiquarianism. By implication, antiquities' looting – namely, the undocumented, self-interested, and profit-related removal of antiquities – stood at the opposite end. Meanwhile, definitions and guidelines, national legislations, and international conventions regarding the scientific, ethical, and professional treatments of ancient materiality were and continue to be established (*see* AIA 2018; CIfA n.d.; EAA 2009; SAA 1996).

To grasp the magnitude of the problem that looting causes for archaeologists, one needs to understand the centrality of context to archaeological research. Context is "where an artefact is found and what is found with it [. . .] the set of relationships among artefacts and between artefacts and their surrounding structures" (Brodie 2006: 52). Archaeologists maintain that coherent historical information comes about only through the systematic study of context. It is thought that objects, in their context of discovery, can provide insight into past cultures; objects which seem insignificant on their own may acquire great informational value if found next to other objects or far removed from their usual area of distribution. Accordingly, when there is undocumented digging and removal of antiquities, archaeological context is believed to be destroyed and historical information lost.

Researchers of the global traffic in looted cultural objects assert that the problems arising from looting extend beyond the destruction of context, as unprovenanced antiquities, despite their unlicensed excavation or illegal export, are sold and owned in a country other than that of their origin (Trafficking Culture 2018a). In the context of state judicial systems, binary distinctions such as criminal vs. non-criminal may conceal cases that are considered suspicious when seen from an archaeologist's point of view, and end up falling into the legal category, evading conviction. Due to the lack of efficient national patrimony laws or due to incompatibilities between different state laws regarding the protection of cultural heritage, it is common for an illegally excavated antiquity when transferred across territorial boundaries to be recognized as legal outside its country of origin. Objects are granted a legal status, provided there is appropriate paperwork that proves a "legitimate" title to the object "that the assumed owner is the owner and has full rights of ownership" (Carman 2005: 19). Another route into legitimacy is when objects are "published in an academic paper or exhibition catalogue" and their suspicious origins are "quietly forgotten" (Brodie 2002: 2). As such, the antiquities' trade is dominantly viewed as a trade that converts a "looted artefact into legal art" (Elia 1995: 245).

In an attempt to acknowledge this dubiety in academic analytical terms, it is common for researchers to use the notion "illicit" in order to "convey the perceived suspect origins of artefacts which cannot be, or have yet to be, proven illegal" (Mackenzie 2014). In effect, dominant references to looting across the archaeological literature presuppose Colin Renfrew's (2000: 15) definition, which describes it as "the illicit, unrecorded and unpublished excavation of ancient sites to provide antiquities for commercial profit." This conceptualization applies to a wide range of undocumented excavations discussed in archaeology, mainly emphasizing their illicit context and commercial intent.

Economically driven motives concern a wide social network comprising the multilevel economic system of the antiquities market (Brodie 2012; Campbell 2013). The term "subsistence-diggers" (Hollowell 2006; Matsuda 1998) is commonly used in order to denote those who first engage in the illicit excavation of archaeological sites and initial transaction of cultural objects. The real commercial profiteering, however, is claimed to implicate those who comprise the further levels of the social network, bringing significant amounts of economic profit to traffickers, as well as cultural capital to collectors and auction houses. It was in this context that Elia asserted that "collectors are the real looters" (Elia 1993: 17).

Vandalism and Looting in War Contexts

Although there is indication to support that looting exists in all countries (for a recent survey see Proulx 2013), the phenomenon of vandalism, aside from the forcible removal and misappropriation of goods, has been particularly associated with contexts of war or conflict. There, the deliberate destruction of sites and monuments is denoted as a series of acts whose purpose is to intentionally eliminate or exploit the cultural heritage of the conquered, while causing the impairment of their identity. Such implication is rooted in the dominantly Western discourse that regards culture as a bounded entity and links identity formation to material culture and claims of ownership.

Surges of vandalism and looting are claimed to be observable today in the wars of the Islamic State network (*aka* ISIL, ISIS, ISI, Aqi) and their claimed pursuit to eliminate the pre-Islamic past. Following the wars in Syria and Iraq, the term "cultural genocide" (Stanton 2015) was once again brought to the fore of analysis (*c.f.* Lemkin 1973: 79), reflecting the resurgence of the matter and impact of looting/vandalism phenomena since World War II and indicating the upgrade of their status from geographically bound cultural problems to globally pervasive security issues. It is in light of these developments that the policy toward these matters is claimed to have become more preemptive than reactive (Nemeth 2016), and it concerns national as much as international agencies, the private as much as the public sector, and, in some cases, cultural heritage specialists as much as counterterrorism officials and cultural institutions as much as security departments (*see* Bogdanos 2005).

In this context, discussion goes beyond practices of "subsistence-digging" as it makes mention of "militant" diggers, who execute the looting of antiquities and use the profits either from their trade (Baker and Anjar 2012; Osborn 2015) or from selling digging permits and charging transit fees (Heissner et al. 2017), in order to fund for their arms procurement. As for the form and purpose of the vandalism involved, these are regularly ascribed to categories such as shelling, gunfire, and army occupation (Cunliffe 2012).

The proclaimed link between war and cultural damage in the form of vandalism and looting, led to developments in the field of law. The international legal framework responsible for the protection of cultural heritage has its roots in the "Lieber Code" of the American Civil War, which instructed soldier conduct in the context of war, one that concerned – among many things – behavior toward buildings and objects of cultural value. The *Hague Conventions* of 1899 and 1907 addressed further the conduct toward cultural heritage during warfare, setting the groundwork for the eventual adoption of the *Hague Convention for the Protection of Cultural Property in the Event of Armed Conflict* in 1954, focusing exclusively on the protection of cultural property. Ever since, the international response has been variously complemented, with the 1970 *UNESCO Convention on the Means of Prohibiting and Preventing the Illicit Import, Export and Transfer of Ownership of Cultural Property* setting a turning point in the international field of cultural protection. A recent UN development that is projected as a strengthening and enforcing strategy to the existing regime is the cultural peacekeeping initiative, where troops are deployed to protect cultural heritage from destruction (*aka* Blue Helmets for Culture). It is a resolution that aims to include "a cultural component in the mandates of peacekeeping interventions where cultural heritage is at risk" and to create "a task force of experts in the protection of cultural heritage" (Foradori 2017).

The role of national and international law enforcement in the effort to curtail the phenomena of vandalism and looting is generally acknowledged; however the question of its effectiveness remains open. The tangible impact of laws is sometimes conditioned by certain factors that are impossible to detect, predict, or calculate. In any case, the publicity and the implicated pressure developed by the legal discourse on these issues are claimed to have had some positive results, echoed in indications of the reduction of the market for certain antiquity categories and the

recovery of lost and stolen artworks (see Art Recovery International 2016).

Raising public awareness about the implications of looting (see SAFE 2018) goes in hand with the effort to document and monitor the ongoing damage. A field of technology that archaeologists use and has improved exponentially is in the area of high-resolution satellite imagery, using sources such as Google Earth (*for a list of references, see* Trafficking Culture 2018b) and NASA (Coleman and Quijada 2010). This method permits research across vast regions, even in places that are unsafe or difficult to access. Lists of sites (*see* Looted Heritage n.d.; UNESCO World Heritage Centre 2018) and objects (*see* ICOM 2018), as well as maps of areas affected by vandalism and looting, are constantly being created and updated (*see* APAAME 2017; EAMENA 2016; The Antiquities Coalition 2018). One of the latest developments is the creation of an online platform that allows satellite imagery access to a global network of citizen explorers (crowdsourcing) in order to record new archaeological sites and map looting activity (*see* GlobalXplorer 2017).

Alternative Approaches to Vandalism and Looting

Alternative approaches to acts of looting arise from the fields of anthropology, post-processual, indigenous, ethnographic, or public archaeology, throwing light upon the social, cultural, and political circumstances that underlie their contexts. Critical in this respect was the conception and emergence of the term "subsistence-digging." It represented the first break with the negative outlooks toward looting as it described the undocumented excavation and sale of cultural objects that supports the traditional subsistence lifestyle of certain local communities (Heath 1973; Staley 1993). As a notion, it is claimed to echo the idea of "subsistence farming and implies that the person engaging in the activity has few other economic opportunities; that they are looting for survival, not profit" (Yates and Brodie 2012).

Since then, scholarly work has focused the attention upon the sociopolitical circumstances that surround nonprofessional diggers in both Western and non-Western contexts. They depart from the idea that undocumented digging is legal or is treated as socially acceptable and justified (Hollowell 2006) and it responds to various on-the-ground conditions that extend from government corruption (Stark and Griffin 2004) to grassroots resistance (Kersel 2007). They concentrate on diverse motivations and interests, which, besides subsistence, in many cases concern connection to place (Antoniadou 2014; Colwell-Chanthaphonh 2004; Trodden van Delzen 1996).

The sympathetic turn toward the discussion on looting extends to and characterizes the larger discourse on conceptions of destruction. While criticizing Western ideas about heritage preservationism and questioning their universality, some scholarly accounts recognize vandalism's affordance of cultural significance (Merrill 2011) or accept destruction as a natural and inevitable dimension of heritage in the context of a non-hegemonic theorization (Holtorf 2006).

Vandalism and Looting: Destruction, Preservation, and the Theft of the Past

Eric Taladoire
Archéologie des AmériquesUMR 8096,
Université de Paris 1 Panthéon Sorbonne,
Paris, France

Introduction

The llama is an animal from the highlands of the Andes mountain range. The recent identification (Goepfert 2011) of massive sacrifices of these beasts in Moche sites suggests the existence of herds along the semidesert coast of northern Peru. This may be explained by human intervention, which encouragingly testifies our ingenuity for the idea of sustainable development, or, and this is less likely, by subtle changes in climate, which are just as important to our concerns about climate change. There are just as many clues obtained from detailed archaeological research as there are testimonies that may have been destroyed once and for all through looting in a search only for the rich funerary mask, or the beautiful object that can return a substantial profit. The looter and its corollary, the buyer collector, who may even be his sponsor, thus commit theft of information, which is harmful to the common good.

Large parts of the past are gone forever. Regarding ideofacts, tastes, beliefs, and rituals, the loss is immeasurable. Regarding ecofacts and artifacts, even at sites that are well known and identified, it is at the cost of a slow and painstaking work, spread over many years that archaeologists are able to draw relevant information from the preserved relics in order to reconstruct the social life of objects. Conversely, the search for the beautiful object, which is illicit and, consequently, clandestine, can only be undertaken by a brutal, and hence, destructive intervention.

Whereas the archaeologist's task is to ensure the protection of the past and the common interest, by contrast, the collector's task is only motivated by a search for private benefit in a speculative perspective. According to Interpol, after drugs, arms, and human trafficking, the looting of artworks ranks fourth in organized crime. However, it needs to be taken into account that the traffic of works of art is often used in laundering drug money, and that looting is a source of potential revenue for criminal organizations to buy weapons.

Admittedly, these are extreme cases. Collectors and art dealers are quick to reply that what motivates their action is the fact that they will ensure the conservation of works from the past, and in doing so, they contribute to a common struggle against their destruction. It is a fact that many major or minor works, since time immemorial, have suffered from multiple causes of destruction. The first cause is clearly natural destruction, including from slow to rapid disintegration of organic matters

Vandalism and Looting: Destruction, Preservation, and the Theft of the Past, Fig. 1 Map of Copan site (Honduras), showing the erosion of the Acropolis by the river

to full catastrophes (mudslides, earthquakes, etc.) (Fig. 1). Superimposed over this natural degradation is mass destruction by people: plundering and looting punctuate the history of humanity, whether in Rome, Egypt, right to the recent world wars and the holocausts of books by the Nazis. More recently, and despite the efforts of preventive archaeology (Martínez Muriel 1988), increasing urbanization and the ravages of modernity have amplified these destructive phenomena. Again it should be stressed that the destruction is the work of a collective action whose objective is rarely the obliteration of the past. It is essential to clearly differentiate plunder from destruction, plunder being akin to theft for personal interest.

Definition

Closer to our concern is vandalism, which, in an effort to differentiate itself from plunder, still shares a few similarities with it. Less massive, less destructive, it however contributes to inevitable erosion. The visitor who traces graffiti on a monument contributes, through stupidity or ignorance, to its degradation. The unaware tourist, who, happy with his discovery, removes a sherd or an arrowhead on a site, is equally objectionable. Yet these are isolated actions, which simply through their repetition, can have serious side effects. Of greater concern is the use of prestigious sites for staging artistic "events." Concerts with light and sound organized in Egypt, Jordan, and Mexico lead to an uncontrollable influx of spectators who stamp on the remains, and mill around monuments outside demarcated areas. Even more destructive are informal New Age events like those which occur at Stonehenge or Chichen Itza (Fig. 2), whose followers' last concern is to respect the ruins. These vandals' ignorance and contempt finally overlap with fanaticism, such as the Taliban in Bamiyan. This may called damage,

Vandalism and Looting: Destruction, Preservation, and the Theft of the Past, Fig. 2 The celebration of the Spring Equinox at Chichen Itza (Mexico). (Photographed by the author)

vandalism, or even looting, as some Bamiyan objects have allegedly found their way to antique shops.

If vandalism sometimes leads to looting, the latter is more akin to opportunistic or circumstantial looting whose origins date back to Antiquity. Looting is indeed an ancient activity. In Egypt, rich burials had to be protected against grave robbers. Similarly, in Central Asia, evidence of ancient looting has multiplied in recent excavations (Bendezu-Sarmiento and Grizeaud 2011). These ancient lootings are not always intended to recover beautiful objects or wealth. In the tombs of Central Asia, it is sometimes minor parts or bones that were collected rather than offerings. It is possible to also draw a parallel with contemporary examples from sub-Saharan Africa where retrieving objects from burials for other uses than their original indented use is current practice. The same situation has been observed in Guatemala where thieves use the Mayan ceramics and grinding stones for personal use (Hansen 1997). Is that looting? Vandalism?

Examples

It is not intended here to give an historical outline of archaeological looting; however, the case of the New World where the Spaniards seized upon the riches of the Aztec and Inca Empires, in their systematic search for gold should be mentioned. This has resulted in the looting of tombs, or other such excessive depredations, such as in Peru, with the diversion of a stream to cause the collapse of an adobe pyramid (Fig. 3). In parallel, a vast campaign of vandalism is ongoing, with the systematic destruction of the remains of a pagan past that the Spaniards wanted to eradicate (Chamussy et al. 2011). The destruction of the Templo Mayor in Mexico or the burning of Mayan codices by Diego de Landa belongs to the same mind set. These two approaches are "justified" on grounds that are more akin to vandalism or destruction than looting.

During the Renaissance and up to the early twentieth century, we enter the field of antique cabinets of curiosity and museums. Organized collection of archaeological objects, and of natural history by nineteenth-century explorers whose aim was to enrich the collections of European museums, unquestionably comes under the concept of pillage. Some antique dealers, such as Boban (Riviale 2001) in the nineteenth century, played a pioneering role in this questionable area. Whether we are talking about the Elgin Marbles, the sack of the Summer Palace in Beijing, or the removal of Yaxchilan lintels, the topic is controversial (Merryman 2006). There is, however, little doubt that if the victims can rightfully call these

Vandalism and Looting: Destruction, Preservation, and the Theft of the Past, Fig. 3 Overview of the Huaca Cortada, Mochica civilization (Peru). (Photographed by N. Goepfert)

acts organized looting, the goal is to enrich public collections, and, in rare cases only, achieve personal enrichment. It differs from artwork thefts that grew from the first half of the last century, with the discovery of American Indian, African, and Pacific Arts (*Mexico en el Mundo de las colecciones de Arte* 1994).

A significant shift occurred in the middle of the twentieth century with the development of archaeological speculation. Looting acquired the dimensions of a systematic, global phenomenon, with gangs and complex laundering circuits. All archaeologists agree on a definition of looting in three broad categories. Whether we call them opportunistic or occasional, seasoned amateurs or professionals, these terms cover the same reality, even if the boundaries between them are tenuous and permeable (*Arqueología Mexicana* 1996). At the base level, is opportunistic looting, which may follow the fortuitous discovery of an object, or a burial site. Many of the objects discovered in these circumstances constitute, for the discoverer, an exceptional boon. The sale of the object, even well below its market value, may represent for the discoverer the equivalent of several months' income. Under these circumstances, how can one be indignant or make a complaint about them? If the looters limit themselves to selling the fruit of their discovery, they generally escape any conviction. Often, they simply recover or destroy the discovered relics. Here, we find again the notion of vandalism: Many farmers from Petén, for example, recover containers for their personal use (Hansen 1997). Also, think about those communities who prospect, dig, and loot to defend, like in Africa, their territorial claims (Polet 2011). Some Eskimos communities from Alaska assert their right to search and sell their archaeological heritage, thereby denying any justification of archaeological intervention that would deprive them of what is theirs (Meunier 2011).

Whether it involves individuals or communities, there is the temptation to pass from the hazardous discovery to intensive looting, without going beyond a local scale. People steal in their region; they systematically look for objects, but more often than not, without method. In the Valley of Ocosingo (Chiapas, Mexico), looters who became aware of the archaeological interest in mounds near which they had lived for a long time, gutted a minor site in two or three nights, destroying a burial site, but also any objects they found within (Taladoire 2011) (Fig. 4). More seasoned researchers of burial sites in Western Mexico, like some *tombaroli* Italians, know how to identify them and wreak real devastation, even though for the most part, they do not carry out their activities a fair distance away from their village. It takes skill and organization, but they are not looting gangs, acting for sponsors, even though their destruction can reach staggering proportions. In Western Mexico, hundreds of tombs were violated in this way, while the number of examples of scientific digs amounts to only a few dozen. Of the 550 recorded graves in Cerveteri, in Puglia, we evaluate the number of looted graves at 400.

Alongside professional looting, there is organized crime (Meyer 1973; Valdiosera Bermán

Vandalism and Looting: Destruction, Preservation, and the Theft of the Past, Fig. 4 Occasional looting site of Joaquin Rancho Millares, Ocosingo Valley (Chiapas, Mexico). (Photographed by the author)

1985). These are organized groups searching for specific objects, who do not recoil from violence. In 1997, A. Anaya, from the National Institute of Anthropology and History in Mexico, accompanied by epigraphist P. Mathews and some workers, sought to transport the Number 4 altar from the El Cayo site all the way to Tenosique (Mexico), in order to keep it secure. Before they could act, they were surrounded by about thirty armed men, who threatened to kill them. At night, they escaped in a makeshift raft down the Usumacinta River (*Mexicon* XIX: 6, 1997). An opponent of looting, Carlos Catalan, a Guatemalan, was murdered in cold blood. As Richard Hansen writes (1997),

> collecting Pre-Columbian art is often viewed as a justifiable means of preserving the past. It is in fact, a destructive and somewhat violent business, as attested by the recent assassination in Carmelia of Carlos Catalan, a local chiclero who had become a staunch opponent of looting in the Petén.

The same year, the watchman at Tziquin Tzakan in Guatemala was assassinated by looters, and a few days later, the same fate happened to one of the two watchmen at Yaxhá (*Mexicon* XIX: 5, 1997). This violence also manifests itself elsewhere. In 1990, armed men burst on the site of Herculaneum and managed to steal 223 objects from the warehouse. The individuals involved in this violence show no more regard for the pyramids they empty (Figs. 5 and 6), the graves they ransack, than for human life. In their search for valuable objects, they destroy without qualms all that they deem unsalable. Nor do they hesitate to break through protection systems installed to protect excavations.

Looting is not limited to single sites. It also involves institutions. In 1999, a jadeite object from Copán was stolen from the National Museum of Anthropology in Mexico (*Mexicon*, XXI: 6, 1999). Another jade figurine from Copan was stolen from the Museum of Tegucigalpa in 2004 (*Mexicon* XXVI: 5, 2004). Thefts are increasing whether they are at the Louvre, The Museum of Cluny (Paris), of Cairo, or elsewhere. Even if this phenomenon remains relatively rare, it is wholly at odds with the argument that implies that these objects be saved to preserve heritage for all humanity, since these objects were heritage listed as such and therefore cannot be sold, at least not publicly.

One borderline case was the massive looting of the Baghdad Museum in April 2003 during the second Gulf War. The museum suffered three robberies, firstly around 40 sculptures were stolen in the galleries; the second one consisted of 3,100 objects from excavations, which were stored in the reserves; and the third one occurred in the cellars, where more than 10,000 small objects were removed. Of these, approximately 5,500

Vandalism and Looting: Destruction, Preservation, and the Theft of the Past, Fig. 5 Looting trenches recorded on La Muralla site (Guatemala). (After Quintana and Wurster 2001)

items were recovered, including more than 700 seized by US customs. There are still about 8,000 pieces missing, some of which have reappeared on the art markets in Jordan, Lebanon, Japan, and Switzerland. In 1996, the Swiss police discovered more than 10,000 Italian artifacts in four warehouses, with an estimated value of 35 million francs.

It is not only the magnitude, which horrifies, but also the extent of the destruction that it entails. To transport objects easily, and without risks, looters look primarily for medium-sized objects of high value. Small pieces do not always have a sufficient market value and are often destroyed at the site. Major pieces like stelae and sculptures, however, are highly sought. But what to do with a stela measuring 3 m in height, and weighing more than a ton? That is no problem when it is sawn into fragments to be transported by a mule. The case of the stelae of Machaquila, cut into 14 pieces, is far from unique (*Arqueología Mexicana* 1996; Graham 1997) (Fig. 7).

The circulation of stolen or looted pieces in commercial circuits is only possible after a slow process of "money laundering," except when it comes to financed looting, which can be delivered immediately. One must wait years before an object reappears, which complicates the task for those who fight against looting. The objects are sometimes stored in secret places, thus freezing invested funds. Others use complex circuits in order to baffle searchers. In 1998, French customs seized several stolen statues from the San Agustin site in Colombia. They were called "garden gnomes" by their owner. Missing since 1989, they had, before arriving in Nantes, followed a complicated route, via the USA, St. Martin, and Spain to cover their tracks. The major objects are not traded openly, but in what Clemency Coggins calls a black market

Vandalism and Looting: Destruction, Preservation, and the Theft of the Past, Fig. 6 Professional looting trench in the Group II of the Río Bec site (Campeche, Mexico). (Photographed by the author)

Vandalism and Looting: Destruction, Preservation, and the Theft of the Past, Fig. 7 Calakmul Stela (Campeche, Mexico). Is heritage better preserved when it is cut into pieces? (Photographed by the author)

(*Arqueología Mexicana*1996). The Internet plays an increasing role, but the majority of major transactions take place in total obscurity. This apparent discretion may give the impression of little activity, largely contradicted by the amount of funds invested. There are in fact only a few quantifiable data on the illicit trade in cultural property, and there is a fast acceleration, parallel to the increase in looting. Traffickers only have their own interests at heart, duping both sellers and buyers. The occasional looter will only receive a handful of dollars; the professional, on the other hand, is able to demand much more. But the difference between the investment cost and the price demanded of the buyer can be very steep.

The discretion of the market leads to the inevitable consequence of the doubtful authenticity of the objects. The fake market has had a growing success and is attested by catalogs, where the descriptions vary between approximate stylistic attributes and absurdities, such as a piece called "Mexico, Inca period." A code of silence among players in this market does not help collectors. The fake market concerns mostly small objects with little value. Big merchants usually cannot afford to deceive their clients, provided they can avoid falling into their own traps. The experts are far from immune to error in authenticity and within domains that are infinitely better documented; there abound fake Dufy and Modigliani paintings. So, imagine in archaeology! This "industry" of fakes is growing even faster as it meets the tastes of collectors as well as merchants. Selective collecting reflects the owner's tastes and fads, as tastes change and fashion evolves. In the area of Zapotec urns, fake styles have been identified, each one responding to specific years. In this way, we have a fake from 1925, with hair

Vandalism and Looting: Destruction, Preservation, and the Theft of the Past, Fig. 8 Figurine Mezcala (Private collection)

"like a boy," a fake from 1930, and so on (Mongne 1992). While privileging his tastes, the collector, instead of discovering unknown arts, merely reflects his own image. An example of this blindness, which profoundly separates the collector from the archaeologist, is Olmec art. Among some 400 identified Olmec monuments, only the monumental heads, about 20 objects, that is 5 % of the body, experience popularity out of proportion. Could the reason be that apart from their real beauty, these objects refer to a "classic" art with which we are all familiar? The same applies to Mezcala or Inuit art, whose sleek appearance speaks to our fantasies of abstract art. Mezcala culture, appreciated by collectors for its sobriety and the geometry of its forms, is very popular since a collector argued, without proof, that they were dated Preclassic (Fig. 8). Since then, archaeologists have made progress in the identification of this culture and its dating, but so-called experts continue to authenticate based on obsolete typologies without verification or correction. Rectifying the error would cause major disruptions in the market.

In other words, in using their aesthetic approach, founded on subjective criteria and financial objectives, collectors and dealers show their ignorance of the cultures they revel in, and their indifference to this universal heritage, which they so claim to defend. One of the arguments of dealers and collectors can indeed be found in the following statement: In recovering these objects, the governments of countries, which have suffered from looting, have seemingly been unable to protect – they work for the protection of aesthetic heritage worldwide (Hoog and Hoog 1991). Traffickers and some collectors deny then the notion of national heritage, which is the very foundation for the identity of a number of countries. They consider themselves above this "narrow nationalism," thus demonstrating their contempt, or even their racism.

The notion of heritage is not considered in a uniform way (Devisse 1994), and, depending on the countries, it can simply cover the domain of colonial art, or in others extend to all vestiges of the past, or even include the ethnological field. In this context, contradictory notions crop up of national heritage, state-level responsibility, and world heritage, which imply the existence of transnational institutions, in particular UNESCO, ICOM, or INTERPOL (Graham 1997). Faced with this institutional framework, the notion of globalization "entitles" some to believe in an individual responsibility invested in the preservation of works of art. We also mentioned the concept of community heritage, which led some groups to claim ownership of their relics, and, in keeping with the same logic, to prohibit archaeologists to access the sites.

In this complicated environment, the fight against looting is a daunting task, despite the progress already made. Overall, national and international laws have been strengthened or improved (Litvak King et al. 1980). The implementation in many countries of ministries or agencies responsible for cultural affairs, with large budgets, changes the conditions for protecting

and preserving sites. The fight against looting has intensified, and the number of international agencies who dedicate an important part of their activities to this repression has increased. Here and there, this fight achieves satisfying results. The signature by many countries of the Conventions on Illicit Traffic of Cultural Property facilitates negotiations and returns. Several museums or large institutions, like Harvard, have begun a policy of return to the country of origin. Conversely, others, in contradiction with the rules of the ICOM, do not hesitate to buy stolen goods, even when they were reported to the authorities, or even included in the databases readily available. In this way, a museum in Florida acquired a fragment of a sculpture of Seibal, known since 1965, and stolen a few years later (*Mexicon* XXV: 4, 2003). This is far from being the only example. In short, we cannot deny the progress that has already been made, but the art market has in parallel become more structured and more complex. And the monies exchanged far exceed the capacity of law enforcement agencies.

Against the lack of legislative frameworks and their application, the best weapon is through the awareness of the importance of heritage within the population concerned, education, and development. This information is crucial against the disinformation practices by looters, dealers, and even museums where laws are haughtily ignored, objects are decontextualized, and confusion between collecting and archaeology is carefully nurtured. That collectors and dealers are treated as archaeologists is insulting to the professionals who fight against the devastation of sites in order to preserve the past and give it meaning.

A newspaper, which recounts the theft of a Corot from the Louvre in 1998, reported an official response that summarizes the current opinion among specialists in France: "The *less said, the better*." In other words, discretion and the law of silence prevail. This attitude may be justified: Any publicity given to artistic and archaeological looting is likely to encourage more and amplify the problem. Investigations designed to locate stolen objects can only benefit from this silence. However, this position is not satisfactory, because it obscures a recurring phenomenon that affects all countries. The fight against the illicit trafficking of cultural heritage is a global phenomenon. Only large-scale publicity recovered a large proportion of the Iraqi objects that had disappeared. Similarly, it is through training and information that *huaqueros* from Sipan (Peru) have become transformed into vigilant guardians of their heritage, thus benefiting from the upsurge in tourism, an investment of longer duration than plunder (Aimi et al. 2008).

Vandals in Search of the Past

Eric Taladoire
Archéologie des AmériquesUMR 8096, Université de Paris 1 Panthéon Sorbonne, Paris, France

Introduction

Whether they relate to the random collection of small relics by unaware tourists or to graffiti on monuments, occasional acts of vandalism are destructive and open to criticism. The intentional destruction of archaeological monuments, whether it involves large works or the ideological eradication of the past for religious, political, or economic motives, is clearly of graver concern. A less serious aspect of vandalism goes more often unnoticed, even when it is not publicized to great fanfare. It essentially concerns sites that are threatened when they are used for private purposes, such as cultural events.

Key Issues/Current Debates/Future Directions/Examples

For about 30 years, it has become a popular trend to use major prestigious sites for public concerts and artistic events, which bring together a large concentration of spectators. If, in Greece, the opening of sites at night has been authorized for a very long time to allow for romantic walks, the phenomenon worsened in 2009 with free access given to 81 sites within the "Greece by Moonlight" program, authorized by the Ministry of Culture. Other events include the Pink Floyd concert in Pompeii in 1971, the show organized by Jean-Michel Jarre on the Giza Plateau (1999), the recital of Placido Domingo "The Concert of a Thousand Columns" at Chichen Itza (2008), which was a follow-up to Luciano Pavarotti (1997), and other artists. If such events use the sites only as a prestigious setting, which for that matter indirectly showcases them, they raise

various problems. Despite relatively strict controls, the mere presence of thousands of spectators (17,000 people at Chichen Itza), as well as the required technical support (lighting, sound, construction of platforms) inevitably leads to the damage and trampling of buried remains. It is symptomatic that responsible institutions like the National Institute of Anthropology and History of Mexico, openly express their reluctance to use sites in this way. One can question the consequences if such concerts were to take place in sites as fragile as Çatalhöyük.

Professionals are not entirely exempt from accepting responsibility for such destruction in pursuit of the development of their own work. The recent controversy in Mexico concerning the installation of a sound and light show at Teotihuacan (2008) is a striking illustration of this. The setup of the necessary infrastructure resulted in significant damage that later required intensive work and expensive restoration. In other cases, site managers, anxious to give their research wide publicity, or even convinced of the emotional value of the sites, do not hesitate to organize cultural events that go well beyond the traditional scientific discourse. In other words, this development corresponds to a passionate approach, which has become popular among some archaeologists and can cause dramatic consequences.

This use of sites for personal or private means can indeed, for a number of reasons, lead to real appropriation by particular groups, such as members of New Age cults, some of whom claim a link to the past, which may be in part, simply imagined. Some of the most well known are those organized at Stonehenge, Chichen Itza, or Teotihuacan. At Stonehenge, since the site reopened in 2000 (after its closure in 1985, following the Battle of Beanfield), thousands of curious people, Druids, and followers of esoteric cults converge on the site each summer solstice. In 2010, there were no fewer than 36,500 people (6,500 vehicles) that occupied the site. While some show relative respect to the site, others, such as the self-styled King Arthur Pendragon come to feast: Their supporters do not hesitate to climb the monoliths, light bonfires, fight against their detractors, and finally transform the site into a nightclub. The sheer mass of participants is already a factor of destruction, in addition to other damage. Similarly, at Teotihuacan, every year, there are thousands of sun worshipers who climb the main pyramid to receive the positive vibrations of the universe. At Chichen Itza, thousands of other sun worshipers attend each year the descent of the serpent of light along the Castillo pyramid. Whether it matters to them or not, this phenomenon is more likely the result of the secondary effects of restoration, and was not intentionally created by ancient Mayas.

While some famous sites are relatively well protected, many others such as Catal Höyük, Carnac (France), El Tajin (Mexico), or the prehistoric temples in Malta, are threatened with the same problems, and many other problems remain unknown. A few years ago, in Chaco Canyon National Historical Park, intruders sought to practice their form worship in spite of the local traditions, and desecrated a kiva in this way. There are many other examples from around the world.

It is not our primary concern to analyze these beliefs, nor the fragility of their archaeological basis, whether it be the eclectic reclamation of ancient cults, questionable interpretations of the past (like the end of the world in 2012), or even pure nonsense, such as the story of crystal skulls (Walsh 2008). Our concern is simply their multiple consequences for archaeology and anthropology. Of primary concern is the unintentional damage caused to monuments and the destructive trampling of relics, resulting in the potential obliteration of the past. More serious is the appropriation of these relics for private use such as the removal of fragments of buildings for spiritual purposes. Sometimes the rituals themselves are accompanied by voluntary and involuntary damages, such as those that recently occurred at Villa Hermosa (Tabasco, Mexico) with the spill of toxic liquids on about twenty Olmec sculptures. The cost of the clean up was $25,000! These practices involve a form of neo-colonialist behavior, which excludes not only the common tourist, but also archaeologists and others who are responsible for

the preservation of the past, as well as the descendants of the cultures who built these sites. The desecration of sites, to the detriment of communities is another major issue. We have seen above that the desecration of the kiva shocked the Navajos, and required long purification rites. The Shoshone-Paiute and other groups have also criticized these intrusions that question their cultural identity. This phenomenon occurs elsewhere including, for example, the site of Çatalhöyük. This defiance of local traditions and interests has serious consequences for communities. It can lead to the outright closure of sites to archaeologists and visitors alike. This happened with the Quiches of Guatemala. It can also stir up tensions based on bitter memories of colonization and its atrocities. In other words, the dissemination of these beliefs and the multiplication of these rituals raise the crucial issue of whether the past belongs to humanity, or to a specific group. For archaeological research, there are some essential ethical implications. If humanity no longer shares a common heritage, both its collective understanding and its specificities must be questioned.

Vargas, Iraida

Lino Meneses Pacheco
Museo Arqueológico, ULA, Mérida, Venezuela

Basic Biographical Information

Iraida Vargas Arenas is the most influential archaeologists in contemporary Venezuelan archaeology, due to her groundbreaking contributions to research and teaching. She was born in Maracay, Aragua State, on August 7, 1942. She graduated from the School of Sociology and Anthropology of the Central University of Venezuela in 1964.

Iraida Vargas Arenas studied Paleobotany in the Laboratory of Palynology of the Faculty of Sciences of the Sorbonne and the University of Leyden, the Netherlands, under the direction of Thomas Van der Hammen. Upon Van der Hammen's return to Venezuela in 1965, she entered the University of Los Andes where he founded the Laboratory of Palynology, initiating archaeobotanical studies in Venezuela. With fellow archaeologist and life partner Mario Sanoja Obediente, Iraida Vargas Arenas carried out regional archaeological investigations in the Cordillera de Mérida, the Maracaibo Lake basin, and the Quíbor Valley. Their work initiated a change of era in Venezuelan archaeology which was then empiricist, normative, and diffusionist.

In 1967, Iraida Vargas Arenas joined the Central University of Venezuela-Caracas as a teacher. This initiated a path that would lead her to investigate the ways of life and work of the Indigenous peoples that occupied the territories of present Venezuelans and gave rise to a series of monographs and scientific articles, some of which were co-authored by Mario Sanoja.

In 1976, Iraida Vargas Arenas obtained her PhD from the Complutense University of Madrid. She participated in the XL International Congress of Americanists held in Lima in 1970, where Latin American Social Archaeology was initiated. In 1974, she published with Mario Sanoja *Venezuelan*

Vargas, Iraida, Fig. 1 Iraida Vargas Arenas

Ancient Formations and Modes of Production. Notes for the study of the integration processes of Venezuelan society (12,000 BC–1900 A.D.) which interpreted the history of Venezuela from a Marxist perspective (Fig. 1).

Major Accomplishments

In the 1980s, Iraida Vargas Arenas organized and participated in the meetings that consolidated the theoretical basis of Latin American Social Archaeology. She was the only woman who participated in these first debates and contributed decisively in the development of the theoretical position of historical materialism. During this decade, Vargas, together with a group of Venezuelan archaeologists, including Mario Sanoja, founded the Venezuelan Society of Archaeologists (SOVAR) in Caracas. They created and edited the GENS journal to spread the works to society.

Archaeology, Science and Society (1990) became Iraida Vargas' top publication. In this book, she postulates a three-category system: economic-social formation (ESF), way of life, and culture. The first category, the ESF, which includes the mode of production and reproduction, is the category that expresses the concrete totality that is nothing more than the society we study. The second category, the way of life, allows us to access the expressions of the particularities that exist in each ESF (Vargas 1990). It represents the historical-social response of a determined human group to the objective natural and social conditions which it must confront and resolve. With this category, it is possible to explain the concrete forms that the ESF acquires in both the totality that it represents, its contradictions, transformations, and specific forms of structuring in a certain place; therefore, with this category we would explain the particular forms society expresses itself in a given territory. The third category, culture, expresses the phenomenal representations of the ways of life (Vargas 1990).

From an ethical-political point of view, Vargas studied and elaborated proposals on the relations between archaeological research, education, and history teaching. With Mario Sanoja, she began to apply Social Archaeology, making it a useful science in the sense of directing archaeological practice toward the search of solutions to the problems that our communities suffer. From this viewpoint, they published *History, Identity and Power* (Vargas and Sanoja 1993), where they discuss the origin of the Venezuelan nation, cultural heritage, historical-cultural heritage, the problems of teaching history in Venezuela, and the role of museums as educational tools, all articulated with the question of cultural identity as a strategic element for the defense of national sovereignty.

By the end of the twentieth century and the first decade of the twenty-first century, Iraida Vargas and Mario Sanoja published a series of highly influential books. The first of these books was *Canoe People. Political Economy of the former Appropriation Society of north-eastern Venezuela* (Sanoja and Vargas 1995). In this book, the empirical evidence obtained in the Venezuelan northeast incorporates, for the first time, discussion of the role of women in the Appropriating Social Formation. In addition, it reveals the gatherers' ways of life of the

Appropriator Social Formation that settled around the year 8000 BC on the Caribbean and Atlantic facade of Venezuela. Sanoja and Vargas' second and third books were *Water and Power: Caracas and the Formation of Caracas Colonial State: 1567–1700* (Sanoja and Vargas 2002) and *Guayana's Ages. Archaeology of a Chimera. Santo Tomé and the Catalan Capuchin Missions 1595–1817* (Sanoja and Vargas 2005). In these books, they study the colonial conditions that were implanted into the Venezuelan territories with European conquest of these lands, that is, the origin of Venezuelan colonial way of life as a particular form of the totality of the capitalist social formation. Iraida Vargas developed her ideas in a fourth book, which she sole-authored, *Woman, Women. Origin and Historical Development of Social Exclusion in Venezuela, the Case of Women Collectives* (Vargas 2006). In this book, she addresses the contributions of women in social production and reproduction in the Social, Appropriating, Tribal and Colonial Formations to understand the role of women's collectives in the contemporary history of Venezuela.

Through the works described here, and through her teaching, Iraida Vargas Arenas had a profound influence on the development of in contemporary Venezuelan archaeology. She is a pioneer whose work has fundamentally shaped the discipline of archaeology in her country.

Vasiliev, Igor B.

Dmitry A. Stashenkov and Irina N. Vasilieva
Samara Regional Historical Museum, Samara, Russia

Vasiliev Igor Borisovich (15.09.1948–08.08.2004). A famous scientist, a lecturer, and an outstanding leader of the archeological science in the Volga – Ural Region of Russia. He graduated the Bashkir State University (Ufa city). In 1970 he was invited by Matveeva G.I. to the Kuibyshev University as a laboratory assistant of archeology study. At the same time, he organized an archeology club at the Kuibyshev Palace of the Pioneers, which started the school archeology in the city. Since 1974 and till the end, all the scientific work of Vasiliev I. B. was connected with Kuibyshev State University and Kuybyshev Pedagogical Institute, where he had a career from a laboratory assistant position to the head of the archeology and ancient civilization chair position. He organized an archeological club for students and then research-and-development archeological laboratory. In 1979 he defended a dissertation in the Board of Studies of the Archeology Institute at the Academy of Science USSR (Moscow). At the same time, working in Samara, in 1988–1994, he took place in the History and Archeology Institute RAS USSR as a science deputy director (Sverdlovsk). In 1994 he headed in Samara Institute of History and Archeology of the Volga Region. He organized archeological expedition and headed active field works in Samara, Orenburg,

Saratov, Voronezh, Kurgan, Tyumen Regions, Bashkiria, and poor North Caspian Sea Regions. He is the author of the famous archeological artifacts diggings, such as Vilovatoe Settlement, Old Elshanka, Kair-Shak, Tenteksor (Neolithic), I and II Khwalyn barrows, Gundorov settlement (Eneolithic), Ytevsky Kurgan barrow (the Early Bronze Age), and others. Due to active expeditions and museum artifacts exploration, he discovered unknown earlier archeological cultures as Middle Volga Region, Elshanskaya (Neolithic), Samarskaya and Khvalynskaya cultures (Eneolithic), and also Potapovsky, Alekseevsky, and Volsko-Lbishensky culture type (the Bronze Age). Academic interest topics are Eastern Europe neolithization, Indo-Iranian and Indo-European nations protohistory, and the Neolithic, Eneolithic, Volga Region, and Ural Bronze Age periodization and culture classification. Vasiliev I. B. was one of the first archeologists who participated complex researches together with agrologists, anthropologists, and paleozoologists. He cooperated intensively with Russian and foreign archeologists. More than 10 all Soviet Union and International Conferences were organized due to his initiative in Samara city. Vasiliev Igor Borisovich is the author of more than 170 research articles and monographs. He actively replenished his findings with the collections of the regional museum. Due to his and his colleagues efforts, there has been established one of the most famous museums in Samara city – educational museum of archeology of the Volga region.

Vegeculture: General Principles

Tim Denham[1] and Huw Barton[2]
[1]Archaeological Science Programs, School of Archaeology and Anthropology, ANU College of Arts and Social Sciences, The Australian National University, Canberra, ACT, Australia
[2]School of Archaeology and Ancient History, University of Leicester, Leicester, UK

Introduction and Definition

Vegetative propagation, or the asexual reproduction of plants, is commonly associated with traditional forms of cultivation in wet, tropical environments of Africa, the Americas, Southeast Asia (mainland and island), New Guinea, and the Pacific. It occurs to some degree in most agricultural systems. Vegetative propagation is implicated in the emergence of agriculture and early plant domestication in the wet tropical rainforests of South America (Piperno and Pearsall 1998) and New Guinea (Denham et al. 2003), as well as potentially in other parts of the world (Weiss et al. 2006).

The term vegeculture connotes forms of plant exploitation, ordinarily agriculture, that are heavily reliant upon the vegetative propagation of plants (Sauer 1952; Hather 1996; Shuji and Matthews 2002). Vegeculture is usually used to refer to a subcategory of agriculture, horticulture, or food production. However, in addition to its economic (food production) meaning, usage of

the term is now being expanded to encapsulate the cultural and social associations of vegetative forms of cultivation.

Key Issues

Vegetative (Asexual, Clonal) Propagation

> Most perennial plants possess two modes of regeneration: sexual reproduction through seed and clonal reproduction through some form of vegetative propagation. . .. The relative importance of sexual vs. clonal recruitment may vary widely among plant species as well as among populations within species. For example, there are many anecdotal reports in the literature of species having abandoned sexual reproduction for some form of clonal reproduction, at least in some habitats or parts of their geographic range. . .. (Eckert 2002: 279).

The defining feature of vegecultural practices is that planting involves some aspect of the "body" of the parent plant, such as a piece of root, tuber, stem cutting, or sucker that is removed and set into the ground (Sauer 1952: 25; Nakao 1966; Hather 1996). Planting a portion of the plant body involves asexual propagation, perpetuating a genetic clone that is selected for based on desirable phenotypic traits. Although commonly associated with root crops, a range of food plants may be cultivated vegetatively. Plant families commonly incorporated into vegecultural practices are generally derived from the clade of monocotyledons that includes a range of staple food plants, such as true yams (Dioscoreaceae), taros (Araceae), sugarcanes (Poaceae), bananas (Musaceae), and palms (Arecaceae), as well as various supplementary and ritual food plants, for example, gingers (Zingiberaceae).

There are various practices through which vegetative propagation is affected. In the case of subterranean storage organs, a whole or substantial portion of a rhizome, corm, or tuber can be dug up, moved, and reburied for propagation, for example, gingers (*Zingiber* spp.), taro (*Colocasia esculenta*), and some yams (*Dioscorea* spp.) (Hather 1996). For vines, a cutting or slip may be taken and partially buried, for example, sweet potato (*Ipomoea batatas*). Similarly, for a variety of other plants, a portion of the stem can be cut and planted, partially or completely, in the ground, for example, manioc/cassava (*Manihot esculenta*) and sugarcane (*Saccharum officinarum*). For other plants, new suckers that grow around the base of the parent are dug up and replanted, for example, sago (*Metroxylon sagu*) and bananas (*Musa* cvs). A few plants can also be propagated by planting sections of aerial roots, for example, marita pandans (*Pandanus conoideus*).

Through asexual reproduction people are able to establish a high degree of control over the gene pool of cultivated plants. Namely, people select for desired phenotypic traits and are able to establish genetic isolation of the cultivated stock through vegetative propagation. Hereby, people establish greater control of phenotypic traits within the natural range of the plant than is possible under sexual reproduction (which entails continual reproduction with wild populations and other cultivated varieties). The clonally reproduced stock is subject to somatic mutation and, as with all plants, genes may be variably expressed in different growth environments (Gremillion and Piperno 2009).

Vegetative (Asexual) and Seed (Sexual) Forms of Plant Cultivation

Arguably, vegeculture represents a different orientation to plants than in seed-based systems of plant exploitation and cultivation. Vegeculture is based on the exploitation of perennials and the faculty of reproduction from plant parts, whereas seed-based reproduction exploits the sexual reproductive capacity of plants, often annuals (including cereals, legumes, and a range of vegetables) as well as a range of perennials (including some fruit and nut trees).

To exemplify using New Guinea as an example, a whole range of plant types are traditionally cultivated using vegetative propagation, including the following: trees (*Pandanus conoideus*), palms (*Metroxylon sagu*), grasses (*Saccharum officinarum*, *Setaria* spp.), fruiting herbaceous plants (*Musa* spp.), leafy herbaceous plants (*Abelmoschus manihot*, *Rungia klossii*), and root crops (*Colocasia esculenta*, *Dioscorea* spp.). These plants are cultivated for various edible plant parts, including efflorescences/flowers,

leaves, buds, fruits, nuts, stem pith, and a variety of subterranean storage organs (roots, rhizomes, tubers, corms). Indeed, agricultural practices in the highlands of New Guinea were formerly almost exclusively, and still are predominantly, vegetative.

Furthermore, *Casuarina* tree fallowing, a fallow system involving the planting of nitrogen-fixing trees in the highlands, is undertaken by the transplanting of self-sown seedlings. Similar arboricultural practices occur throughout the lowlands of New Guinea, where tree crops have formed a much larger contribution to diets. Trees are usually transplanted through the digging up, movement, and planting of germinated seedlings and saplings, rather than reproduced from the planting of seed.

A vegetative orientation to cultivation has aided the widespread adoption of several food plants introduced to New Guinea over the last few hundred years, such as sweet potato (*Ipomoea batatas*), and manioc/cassava (*Manihot esculenta*) and taro konkon (*Xanthasoma sagittifolium*). Seed-propagated plants are also being widely adopted, including maize (*Zea mays*) and rice (*Oryza* sp.).

Agricultural or horticultural systems based on vegecultural practices have been contrasted with those based upon sexual reproduction using seeds, not only in terms of the mechanics of planting but also in terms of other agronomic, cultural, demographic, developmental, environmental, and social aspects (Harris 1969; Diamond 1997; Hildbebrand 2007). However, rather than being seen as strictly demarcated alternatives, these strategies usually co-occur. Vegetative propagation is often practiced by agricultural societies reliant on the seed-based cultivation of cereals, legumes, and trees. Although this is readily apparent to anyone who is a gardener in the western world – where people continually reproduce perennials as ornamentals in their gardens – this probably also occurred in the distant past. The vegetative propagation of figs (*Ficus carica*) in the Lower Jordan Valley has been interpreted to have preceded, or accompanied, the earliest cultivation of plants there (Kislev et al. 2006), despite uncertainties regarding the timing and significance of the earliest finds (Denham 2007). Similarly, most groups reliant on vegecultural practices may also reproduce plants from seed.

Vegecultural Orientations in Foraging/Hunting-Gathering Societies

Although commonly associated with types of cultivation in different parts of the world, there is increasing evidence that vegecultural orientations existed within some foraging, or hunting-gathering societies. This orientation was manifest as an awareness of a plant's vegetative reproductive capacity in the way people exploited plants, as opposed to directly cultivating them. The current understanding of these practices is limited by a lack of the relevant archaeobotanical, ethnobotanical, and genetic data.

Multiple accounts of Australian Aborigines record people replanting a viable portion of a plant when digging for and collecting tubers (Berndt and Berndt 1993). People may have dug up and collected the majority of tubers, but they were sufficiently aware of the vegetative reproductive capacity of plants to know that new tubers would grow if a viable portion of the plant was reburied. In northern Australia there is circumstantial evidence for forms of vegecultural manipulation involving various plants, potentially including taro (*Colocasia esculenta*) and yams (*Dioscorea* spp.), in the distant past (Jones and Meehan 1989; Denham et al. 2009). In more temperate and desert regions, the distributions of some species of yam (e.g. *Dioscorea hastifolia*; Hallam 1989), *Typha* (Gott 1999), and other tuberous plants such as *murnong*, or daisy yam (*Microseris scapigera*; Gott 1983), are suggestive of sustained human management along vegecultural principles, including potential movement, in the past.

The Social Context of Vegecultural Systems

People practicing vegeculture often transpose elements of the vegetative reproductive capacity of plants onto their social relations and even onto human anatomy (Barton and Denham 2011). Recurrent elements include cloning the "body" or parts of the plant and the trans-generational life histories of many vegecultural staples.

The Kawelka at Kuk Swamp in New Guinea articulate their kinship relationships with

reference to vegetative propagation. The original people, or principal landowners, are "ground-root-men" (*mae pukl wua* in Melpa) (Ketan and Muke 2001) and people who "hold onto the ground bone" (*mae ombil amborom*) (Strathern and Stewart 1998: 87–88). The root binds the people to the ground like plants. New generations, lineages, and subclans emerge from the original clan through time, as stems, shoots, and cuttings emerge from the root; like transplants, people are adopted by or married into other groups (Muke and Mangi 2006: 42–62; John Muke, *pers. comm.* to Tim Denham 2007).

These types of insight on the social implications of vegeculture are being applied to processes in the distant past that currently have low archaeological visibility. An example is the way domesticated rice (a sexually reproduced crop) was adopted by farmers inhabiting Island Southeast Asia around 4,000–3,000 years ago (Barton and Denham 2011). How was the planting of rice from seed grafted onto preexisting vegetative cultivation practices, and what were the social implications for people inhabiting that vegecultural world? Rather than a model of rapid, widespread adoption for food production, recent interpretations focus on the gradual incorporation of rice as a status crop (e.g., Barton 2012).

Vermillion Accord on Human Remains (1989) (Indigenous Archaeology)

Cressida Fforde
National Centre for Indigenous Studies, The Australian National University, Canberra, ACT, Australia

Introduction

The Vermillion Accord is a set of six clauses adopted by the World Archaeological Congress (WAC) which concerns science and the treatment of the dead. It is of high significance to the archaeological profession and Indigenous groups, and its development and adoption is a key moment in the history of the reburial movement. Created in 1989, and adopted by WAC in 1990, the Vermillion Accord was the first document developed *together* by archaeologists and Indigenous people to provide a set of principles for behavior, decision making, and mutually agreed ethical approaches to the question of archaeological (and other scientific) interest in the mortal remains of the dead. At a time of high concern around issues raised by the reburial movement, when tensions could run exceptionally high and the media represented the debate as intractably polarized, the Vermillion Accord stands out as a demonstration that "mutual understanding and respect were possible between Indigenous people and archaeologists" (Zimmerman 2002: 91). Indeed, *respect* is the key word throughout the Accord, and forms the fundamental basis for agreement and decision making. Additional important aspects of the Accord are that it includes fossil hominids and, although developed out of the reburial debate, is not designed to be exclusively concerned with the Indigenous dead.

Definition

The Vermillion Accord reads as follows:

1. Respect for the mortal remains of the dead shall be accorded to all irrespective of origin, race, religion, nationality, custom and tradition.
2. Respect for the wishes of the dead concerning disposition shall be accorded whenever possible, reasonable and lawful, when they are known or can be reasonably inferred.
3. Respect for the wishes of the local community and of the relatives or guardians of the dead shall be accorded whenever possible, reasonable and lawful.
4. Respect for the scientific research value of skeletal, mummified and other human remains (including fossil hominids) shall be accorded when such value is demonstrated to exist.
5. Agreement on the disposition of fossil, skeletal, mummified and other remains shall be reached by negotiation on the basis of mutual respect for the legitimate concerns of communities for the proper disposition of their

ancestors, as well as the legitimate concerns of science and education.

6. The express recognition that the concerns of various ethnic groups, as well as those of science, are legitimate and to be respected will permit acceptable agreements to be reached and honored.

Key Issues

The Accord was developed by participants at the first Inter-Congress of the World Archaeological Congress, which was held in Vermillion, South Dakota, USA in 1989. Entitled "Archaeological Ethics and the Treatment of the Dead," the Inter-Congress brought together more than 200 people from 20 countries, many of them Indigenous – including 50 Native Americans from 27 different nations and Indigenous delegates from Australia, Scandinavia, New Zealand, and Africa (Zimmerman 2002: 91). They had come together to discuss a matter of great (and continuing) concern to Indigenous groups – that the mortal remains of their dead were held in museums without the permission of their communities of origin and against their wishes, and that requests for their return were being met with refusal, at that time, from almost all holding institutions.

Many of these remains (and by far the majority that were housed in European institutions) had been acquired in the nineteenth century for the purposes of racial science. Others, most notably in the previous "colonies," had also been gathered in more recent years for modern archaeological and physical anthropological study. Although little information was widely available in the 1980s, subsequent historical research driven by Indigenous concerns, revealed that collections were extensive, both in number and in terms of geographical region, and were to be located in museums (national, regional, and local), universities and private holdings both in their country of origin and internationally.

While history indicates that Indigenous groups had always been concerned at the removal of remains, opposed it when they could and had in a few known instances requested returns (Gunson 1974: 1, 84; Turnbull 2002; Fforde 2004: 61–75), the reburial issue came to the fore in the mid-1980s. A small number of significant returns had occurred prior to this date, but it was only in the 1980s that Indigenous concerns were made loud and clear to the archaeological, anthropological, and museum professions (Hubert 1989; Mulk 2009). By the time of the Inter-Congress, the reburial issue could be considered the single most important point of debate for these stakeholders: for Indigenous groups it raised deep concerns about the treatment of their dead, and for scientists and museum professionals it raised questions of profound significance about ethics, the future of research, and the role of museums (Layton 1989; Weatherall 1989; Watkins 2003; Turnbull and Pickering 2010).

As noted by US archaeologist Larry Zimmerman, who hosted and helped to organize the Inter-Congress, the Vermillion meeting was not the first cooperation between Native Americans and archaeologists on the issue of human remains (2002: 91). Nor was it the first time that the issue had been debated at an international level – this had occurred at the first meeting of WAC in Southampton, UK in 1986. Indeed, the decision to hold the Inter-Congress had been taken by the organizing committee at the 1986 meeting due to the presentations, discussion and debate about the issue brought to the Congress by its Indigenous participants (e.g., Hammil and Cruz 1989; Hubert 1989; Richardson 1989 and see Turner 1989). However, the Vermillion Inter-Congress was the first time that archaeologists and Indigenous people were "able to come to agreement on working toward real solutions" (Zimmerman 2002: 91), and the result was the Vermillion Accord.

Initial reaction to the Accord from the archaeological community was varied. The Society of American Archaeology disagreed with its contents, whereas the Canadian Archaeological Association and the Australian Archaeological Association adopted the Accord with some changes to reflect local circumstances (Zimmerman 2006: 89 and see Watkins et al. 1995 for a review of policies). Shortly after the Accord was adopted, and following two decades of lobbying by Native American groups, *The National Museum of the American*

Indian Act (1989) followed by *The Native American Graves Protection and Repatriation Act* (1990) were made law in the USA. While these significant pieces of repatriation legislation should not be seen as a result of the Vermillion Accord, its adoption demonstrates clear awareness of the need to provide real solutions to the repatriation issue at that time, and it is legitimate to argue that it contributed to the passing of this legislation. WAC continued to develop policy in this area, adopting its Code of Ethics on Members Obligations to Indigenous Peoples in 1990, and the Tamaki Makau-Rau Accord on the Display of Human Remains and Sacred Objects in 2006.

The Vermillion Accord was adopted at the end of a decade which had witnessed considerable efforts by Indigenous communities to seek the return of their dead, had resulted in a small number of returns to communities, and demonstrated that some archaeologists had begun to change their stance around retention. Throughout the 1990s, countries with Indigenous claimants moved to develop pro-repatriation policies, but in Europe only a small number of museums agreed to return remains, and these were almost all from the UK. Changes gathered pace in the 2000s, with more remains returned to Australia and some to New Zealand and North America, including from many UK institutions that had steadfastly refused requests in previous decades.

While the reburial debate was (and in some areas continues to be) deeply divisive (see Hubert 1992; Jones and Harris 1998; Mulk 2009), both within the scientific profession and between scientists and Indigenous groups, the Vermillion Accord was an early signal not only that scientists and Indigenous groups could come to agreement, but also that polarized arguments suggesting that, for example, Indigenous groups were "anti-science" or that all scientists shared the same views, were not the reality. Fundamentally, the Accord may be seen as an early signal of the opening up of dialogue between Indigenous groups and those professions which seek to study their past, the beginning of the ceding of exclusive control by the latter and the emergence of the development of collaborative partnerships around cultural heritage (Zimmerman et al. 2003; Phillips and Allen 2010; Turnbull 2010). It can also be viewed as an example of the significant role that the World Archaeological Congress has played in this shift.

Introduction

The World Archaeological Congress (WAC) adopted the Vermillion Accord on Human Remains at its first Inter-Congress, held at Vermillion, South Dakota, in September 1989. The Accord comprises six principles that have since greatly influenced debates and the formulation of ethical policies in respect of scientific use of human remains by archaeologists and researchers in cognate disciplines.

Definition

The first four principles of the Accord commit WAC members to observe and advocate the following:

1. Respect for the mortal remains of the dead shall be accorded to all, irrespective of origin, race, religion, nationality, custom, and tradition.
2. Respect for the wishes of the dead concerning disposition shall be accorded whenever possible, reasonable, and lawful, when they are known or can be reasonably inferred.
3. Respect for the wishes of the local community and of relatives or guardians of the dead shall be accorded whenever possible, reasonable, and lawful.

4. Respect for the scientific research value of skeletal, mummified, and other human remains (including fossil hominids) shall be accorded when such value is demonstrated to exist.

The Accord further specifies that:

5. Agreement on the disposition of fossil, skeletal, mummified, and other remains shall be reached by negotiation on the basis of mutual respect for the legitimate concerns of communities for the proper disposition of their ancestors as well as the legitimate concerns of science and education.
6. The express recognition that the concerns of various ethnic groups as well as those of science are legitimate and to be respected will permit acceptable agreements to be reached and honored.

Key Issues

The Accord was drafted by members of WAC and representatives of indigenous communities wanting to find common ground after a decade of organized, vigorous campaigning – notably by North American Indians and Australian Aboriginal people – to put an end to the unrestricted exhumation, study, and keeping by museums, universities, and other scientific institutions of indigenous skeletal remains and grave goods. Discussions at Vermillion further brought to light evidence that North American, Australian, and European museums and medical school collections included bones and soft tissue structures from the bodies of indigenous people killed during the nineteenth century in frontier clashes with settlers, police, or military personnel.

In adopting the Accord, WAC committed its members to respect the rights of the dead to burial in accordance with ancestral or contemporary religious beliefs and practices and to recognize the rights of those with familial, communal, or cultural obligations to care for the dead to do so without hindrance or constraint. At the same time, by the Accord, WAC formally declared its commitment to promoting the scientific study of human remains for the benefit of all humanity.

What was most significant about the adoption of the Accord was that it affirmed the importance of recognizing the value of research on human remains but did so after emphasizing the need to respect the wishes of those with not just familial but obligations of "guardianship" to the dead. WAC members unanimously agreed that only by scientists respecting the continuing rights of indigenous people to treat remains in accordance with their religious or cultural beliefs, would they gain sufficient moral standing to try and convince those with affinities to the dead to permit remains to be used for research.

This was a major step beyond how archaeological and other research communities had previously responded to increasingly determined campaigning by indigenous people for ownership and control of the fate of remains. Up until this time, researchers and museum curators were in general ready to agree to surrender for reburial the remains of known individuals, but publically affirmed their opposition to the reburial or cremation of all other remains on the grounds that this would deny science evidence of potentially great value in producing new knowledge of our species' evolutionary development.

On the face of it, the principles set out in the Accord appear to stand at odds on the fundamental issue of recognizing that both researchers and indigenous people have legitimate concerns in respect of the dead. Indigenous intellectuals and postcolonial scholars have argued that justifying preservation and unrestricted research on remains on the grounds of potentially producing new knowledge of benefit to all humankind, or people sharing a common genetic ancestry, risks promoting the interests and ambitions of scientific practitioners over the religious beliefs and cultural traditions of peoples who, in many instances, continue to struggle to overcome the ingrained psychic and material legacies of colonialism. Researchers with interests in human remains have countered that recognizing culturally based claims of rights to determine the fate of human remains risks losing our means of gaining new insights into our evolutionary history or possibly understanding the causes of disease in specific populations. The most strident opposition to returning remains to the care of

indigenous communities came from scientists who believed that they were defending the heritage of humankind against "indigenous creationists."

In practice, however, the Accord has contributed greatly to the development of new and mutually beneficial relations between indigenous communities with affinities to remains, research communities, and museums. Its principles have been adopted by or greatly influenced thinking about the ethics of research on human remains within government circles, international and national scientific societies, and the museum sector. The Accord was used in the early 1990s by several Australian State Governments as the basis for developing new policies in regard to Aboriginal and Torres Strait Islander human remains. In 1991 the Council of Australian Museum Directors (CAMD) drafted a new national policy for museums and Aboriginal Australian people. In regard to human remains, CAMD endorsed the Vermillion principles, reasoning that they would permit acceptable agreements to be reached and honored. Since then, the Accord has informed discussions among museum professionals in many countries worldwide, similarly resulting in the adoption of new policies and practices governing the keeping, or surrender to community claimants' ownership and control, of human remains and cultural property of profound significance.

The Vermillion principles were incorporated within WAC's 1990 Code of Ethics and used in 2006 in developing the Tamaki Makau-rau Accord, which addresses the sensitive issue of displaying human remains and sacred objects in museums and by other media. Moreover, the Code and Tamaki Makau-rau reflect an expansion of the Vermillion principles to recognize that communities with legitimate claims to remains held in scientific collections may include, but are not limited to, ethnic, racial, religious, traditional, or indigenous groups of people.

Vertebrate Taphonomy in Archaeological Research

Peter W. Stahl
Department of Anthropology, University of Victoria, Victoria, BC, Canada

Introduction

Broadly applied, taphonomy is the study of what happens to objects after they leave the biosphere (living contexts), enter the lithosphere (buried contexts), and are subsequently recovered and studied. Taphonomy is of interest to any scientific discipline that investigates the buried record, including archaeology, paleobiology, paleontology, and soil sciences. Although the methodological framework of taphonomy can be applied to the study of practically any kind of material that was once buried, including ceramics and lithics, its archaeological application usually involves the study of preserved organic residues. Vertebrate taphonomy is further restricted to the study of preserved skeletal specimens that originate from a subphylum of animals who share a number of characteristics but importantly possess a living endoskeleton of cartilage and bone. These consist of specimens

from zoological classes of living jawed vertebrates that are often recovered through archaeological excavation, including Chondrichthyes (cartilaginous fishes), Osteichthyes (bony fishes), Amphibia (amphibians), Reptilia (reptiles), Aves (birds), and Mammalia (mammals).

Definition

Taphonomy has been described as "the study of natural processes of preservation and destruction" (Behrensmeyer 1984: 558). Vertebrate taphonomists are interested in studying all of those processes that contributed to the preservation and/or destruction of bone specimens as they progress through successive, often nonlinear and recursive, stages from death through decomposition, burial, recovery, analysis, and curation. The recovered sample can display preserved evidence of these processes in the form of a taphonomic overprint. Taphonomists attempt to (1) identify the specific agents (physical cause of modification) that have contributed to preservation and destruction based on surviving clues (taphonomic effect, trace, or signature) in the archaeological record, (2) recognize how the recovered samples differ from the originally accumulated and deposited assemblages and evaluate the significance of differential preservation to subsequent interpretation, and (3) infer a relative chronology (taphonomic history) of taphonomic processes (dynamic actions of taphonomic agents) that have affected the assemblage (Behrensmeyer 1984; Lyman 1994).

Historical Background

Taphonomy is a neologism that was first introduced into the literature by Russian paleontologist Ivan A. Efremov. Derived from the Greek *taphos* (burial) and *nomos* (law), taphonomy concerned "the study of the transition (in all its details) of organic remains from the biosphere into the lithosphere" (Efremov 1940). Although its name is of recent derivation, interest in the processes that form the buried record has a long history in archaeology, one which originates at least with the early nineteenth century curiosity surrounding the relationship between human artifacts and extinct Pleistocene mammals (Grayson 1986). In archaeology, taphonomic studies generated increasing attention during the latter half of the twentieth century and gained more recent momentum due to controversial interpretations about early hominid behavior that were inferred from associated bone assemblages (Binford 1981; Brain 1981). Today, vertebrate taphonomy has become such an essential tool in the analysis and interpretation of archaeofaunal assemblages that it is difficult to consider it as a separate aspect of study and anything other than a standard component of practice which is necessarily basic to all analyses of archaeological bone specimens.

Key Issues/Current Debates

Analysis of vertebrate specimens recovered from excavated archaeological contexts is generally used to establish inferences about past subsistence and ecological contexts. Preserved archaeofaunal assemblages are usually composed of two related subsets of bone specimens that were originally accumulated at the site of deposition: (1) intentionally by humans as by-products of subsistence and (2) by any number of agents that were either incidental to human activities or not. Both subsets can be used in paleoecological inference; however, subsistence inferences tend to emphasize the analysis of specimens that were intentionally accumulated and deposited by humans for subsistence purposes. Although intuitively obvious, it is important to emphasize that both subsets of archaeofaunal specimens in the recovered sample differ quantitatively and qualitatively from the target population of interest, the living organisms that were associated with any area or time of archaeological attention (Fig. 1). Specimens that were recovered from the context of archaeological interest were selectively accumulated and deposited by various human and nonhuman mechanisms. After their deposition, specimens were further affected by a potentially wide range of taphonomic processes that could have subsequently modified their spatial arrangement and/or qualitative and quantitative attributes before and after burial and prior to eventual

Vertebrate Taphonomy in Archaeological Research, Fig. 1 Schematic taphonomic framework emphasizing the relationship between a recovered and analyzed archaeological sample and the archaeologist's target population of interest

recovery in archaeological excavation (Clarke and Kietzke 1967; Grayson 1981; Lyman 1987; Wilson 1988). Both subsets are important to archaeological interpretation; however, it is crucial to consider their relationship to the original target of interest and their relevance and reliability in terms of the questions that we ask and the answers that we seek. It is important to consider the potentially different taphonomic histories that formed the sample. Taphonomic evidence is potentially accessible through the study of traces or signatures that might have preserved in the recovered specimens and their associated depositional contexts. The recognition of signatures and their use in interpretation is established through middle range research which experientially examines and evaluates causes and their effects (Binford 1981).

Factors that contributed to these histories can include various processes involved in the perimortem and postmortem accumulation, deposition, dispersal, and destruction of the archaeofaunal assemblage, in addition to technical and methodological aspects involved in its archaeological recovery, analysis, identification, and curation. Although taphonomists search for clues in the study sample and associated archaeological contexts, they must remain ever mindful of pervasive equifinality (similar outcome produced by different events). Multiple effects may be produced by one process, similar effects may be produced by different processes, or observable effects may be obscured through subsequent assemblage formation.

Perimortem Assemblage Accumulation and Deposition

Most vertebrate archaeofaunal assemblages were originally accumulated and deposited through varying processes, and because of the different questions asked by archaeologists, it is important to distinguish between the different taphonomic

histories represented in the sample. Specimens of animals that were selectively accumulated by humans for subsistence purposes can contribute to paleoecological inferences; however, these are relevant to conditions in areas from which they were selectively procured and subsequently transported. Specimens whose accumulation was incidental to human consumption can provide information about ecological conditions in and around the immediate area of deposition. They may represent the preserved specimens of animals that were deposited at the time of human occupation, or they may embody evidence of later intrusion into site contexts. These specimens often consist of bones from smaller anthropic (associated with humans) taxa, like rodents that are generally treated as nuisance rather than prey items. While alive, they thrive in the conditions that are created in and around human activity, and after death their skeletons can be subsequently incorporated into the immediate sedimentary record through accidental entrapment, fire, flood, or natural death in underground burrows. Relevant signatures can be identified in preserved specimens and their associated contexts. High concentrations of anatomically complete skeletons with relatively, little perimortem damage, and relatively intact anatomical articulation can suggest accidental in situ death and subsequent decay. Pale surface coloration of preserved bone specimens that contrasts with otherwise soil-stained assemblages might suggest intrusion. Associated contextual information as visible krotovinas (soil-filled burrows) or vertical/spatial association with features that inhibit escape can be crucial for establishing the mechanism of accumulation, as can the ecological and biological characteristics of the identified taxa (Stahl 1996). Bone specimens can be accumulated, modified, and subsequently deposited as prey items by human and nonhuman predators. Prey taxa can be identified through digested bone specimens deposited in scats and pellets, whereas predators can be identified through modifications that occurred during capture, consumption, and digestion. Signature criteria are established through actualistic study and consist of corroborating evidence like tooth marks, acid etching, patterned bone fragmentation, skeletal element representation, adhering scat material, archaeological context, and ecological information (Andrews 1990; Stahl 1996). Regardless of which predator accumulated and deposited them, preserved prey specimens can provide information on ecological conditions. Carnivores, and especially domestic dogs when present, can accumulate, modify, spatially rearrange, and deposit bones that can subsequently be incorporated into the archaeological record. In particular, tooth mark morphology, frequency, orientation, and patterning on preserved bone specimens are compared to results from actualistic studies and used to establish their involvement in assemblage formation (Binford 1981; Brain 1981).

Bones that were accumulated, modified, and deposited by humans for subsistence purposes are often identified by similar criteria, including patterned bone breakage, tooth marks, and carcass disarticulation; however, a wider range of potential data are implicated primarily because of the highly varied nature of cultural consumption. Butchery scars produced by tools are noted for their location, orientation, and morphology, yet these are often rare. Interpretations based solely on patterned breakage and disarticulation are especially prone to equifinality as these forms of alteration are often guided by anatomical rather than predator-specific variables (Hill 1979; Lyman 1987b). Archaeologists record the extent and anatomical location of discoloration on bone surfaces that have been exposed to heat as important evidence for human consumption. Bone discoloration can be compared with results from actualistically derived studies that associate color with temperature in order to assess the degree of exposure to heat (Shipman et al. 1984). However, bone discoloration is not necessarily a product of cooking, as many cooking techniques leave no trace of direct heat modification. Discoloration of bone is more often than not the result of intentional disposal or use as fuel. Sometimes bones used as tools can substantiate human use, as can archaeological context. In any case, the strength of the inference is increased through using multiple lines of evidence.

Postmortem Accumulation, Dispersal, and Destruction

A wide variety of processes can affect the quantitative and qualitative structure of the deposited assemblage prior to burial. Water movement can alternately modify, spatially arrange, winnow, and accumulate bone assemblages. Different velocities and sediment substrates are implicated in the size, shape, and density sorting of bone specimens, particularly those from smaller skeletons which are prone to movement at even low hydrodynamic velocity. Evidence for water movement can be found in patterned spatial orientation of bone specimens, surface modifications, and analysis of sediment matrix (Voorhies 1969; Behrensmeyer 1975). Deposited bone specimens can be subsequently modified or completely removed by animals for mineral consumption and dental maintenance, sometimes leaving visible clues that can lead to the identification of the modifier. Exposed bone that is trampled can produce breakage, surface modification, and size-sorted horizontal and vertical spatial movement. Exposed bone can become weathered over time, and the extent of bleaching, cracking, exfoliation, and disintegration can be used to assess the duration of exposure, ambient pre-burial environments, sequential burial and reexposure, and attritional and catastrophic accumulation (Behrensmeyer 1975). Bone assemblages continue to be altered after burial and during diagenesis through chemical dissolution as the physical properties of the buried bone complexly interact with ambient matrix conditions. Burial environments can also substitute or add to buried bone materials and contribute to breakage or vertical and spatial movement through mechanical pressure. Diagenetic modifications are inferred from comparisons with actualistic studies by means of chemical assays, fracture morphology, coloration, surface changes, conjoinability, and archaeological context (Hedges 2002).

Archaeological Recovery, Analysis, Identification, and Curation

Prior to excavation and recovery of archaeofaunal assemblages, the factors that contributed to the unique taphonomic histories of preserved specimens are outside of the archaeologist's purview. However, the different techniques and screen aperture sizes used in field recovery can strongly affect the qualitative and quantitative characteristics of the studied sample. This can, in turn, affect counting statistics and estimations of assemblage diversity. Increasingly meticulous recovery using fine aperture mesh or water flotation augments the recovery of smaller items which can skew assemblage composition toward domination by smaller specimens. The latter can affect assemblage characteristics by increasing the proportion of smaller animals or indeterminately identified specimens that cannot be reliably identified because they are too small. These factors also implicate the differential fragmentation of specimens, a process which can continue during recovery, and subsequent processing and handling. Fragmentation is relevant to analysis and interpretation only if it preceded recovery and can be accordingly identified by coloration of recent fracture surfaces. Correction factors, comparison of retrieved samples with known recovery results, and actualistically derived affects of differing screen apertures (Schaffer and Sanchez 1994) can be used to assess recovery-related influences. Other evidence for understanding assemblage accumulation and deposition is observed in archaeological contexts during field excavation, including skeletal articulation, intrusion, and spatial/vertical association in feature contexts. Specimen identification is also affected by taphonomic history as denser elements, or portions thereof, are differentially resistant to fragmentation and often preserve with enhanced diagnostic potential. Conversely, differential fragmentation can also obscure identification, as when preserved specimens are too small to be reliably identified. Often, preserved specimens of small-bodied animals may be large enough for identification, whereas large-bodied animals can yield larger indeterminate fragments (Watson 1979). The qualitative and quantitative structure of the sample, how representative it is of the target of interest, and its overall utility for answering research questions are direct outcomes of identification.

Equifinality

Equifinality often confounds interpretations of taphonomic histories and evaluations of the relationship between sample and target assemblages using criteria derived from actualistic studies in middle range research. One taphonomic process may produce different preserved effects. Different taphonomic processes may produce the same preserved effect. Taphonomic processes may produce no preserved effect, or preserved evidence that was available at one point in a taphonomic history may have been subsequently obscured by a later process. Bone destruction and preservation, as defining features of taphonomy, are strongly mediated by the differential structural density of osseous tissue within skeletal elements. Relatively fragile portions of elements are more prone to destruction; relatively harder portions are more prone to preservation. Many different taphonomic processes are implicated as ultimate causal factors that can contribute to differential bone destruction, whereas the proximate causal factor is bone structural density. Taphonomists compare differential bone preservation to experimentally derived structural density values from different portions of the vertebrate skeleton in order to assess whether or not survivorship was influenced by attritional forces whose effects were mediated by differential bone structural density. The procedure can be used as a first-order approximation for exploring assemblage survivorship; however, observations from the recovered specimens and their archaeological context are used to uncover evidence for the ultimate causes behind assemblage preservation. The likelihood that the assessment is a correct one is strengthened through the use of multiple, corroborating lines of evidence (Brain 1981; Lyman 1994).

Subsistence Interpretation

Interpretations pertaining to human subsistence are more reliably derived from the analysis of bones that were originally accumulated and deposited by humans for their consumption. However, the quantitative and qualitative structure of the recovered sample is never isomorphic with the target assemblage. Fluctuations in the basic counting statistic (NISP or Number of Identified Specimens) are affected by various taphonomic processes involved in differential fragmentation, preservation, and recovery (Grayson 1981). Archaeological data are used to identify the kinds of animals that were exploited in the past, which sexes or ages were preferred, and when, where, and how they were procured, processed, and consumed. However, because the exact quantitative relationship between sample and target assemblages can never be known, it is usually difficult to establish anything more than a rough estimate of relative contribution to human subsistence.

Paleoecological Interpretation

Inferential logic in paleoecological study relies on contemporary observations of living organisms. It links existing ecological relationships among analogous living organism with animals identified in the recovered sample that were accumulated and deposited at some earlier period and place of archaeological interest. Findley (1964) previously identified four important problems that are immediately relevant to paleoecological inference building: (1) although the ability to identify animals varies between different elements in different skeletons and can be obscured by taphonomic processes, paleoecological inferences require high-resolution identifications; (2) even where high-resolution identifications are possible, available ecological data may be poorly known; (3) many animals are widely distributed and broadly tolerant of a wide range of ecological conditions; thus, greater emphasis is placed on specific animals that tolerate only a narrow range of conditions; and (4) the relationship between an animal and its not static and can change through time. The quantitative relationship between sample and target assemblages is never isomorphic, and the exact significance of taxonomic abundances in the sample is difficult to determine. Therefore, interpretations that are based on treating identified taxa as variables have a higher likelihood of being incorrect. Treating identified taxa as attributes is the only currently acceptable

approach to paleoenvironmental analysis. Interpretation based on presence and absence, with asymmetrical emphasis on the former over the latter, greatly reduces the chances of inappropriate conclusions. Attribute-level treatment is still vulnerable to problems associated with analogical reasoning and to obstacles created during taphonomic history; however, these problems can be mitigated through reconstructing communities of associated vertebrates. Multiple concordance within an identified suite of taxa overcomes problems associated with archaeological resolution and long-distance transport and strengthens the analogy because the niche of the entire community is narrower than that of any individual component. The possibility that all members of the entire community were affected in the same direction and to the same magnitude is far less than the same possibility affecting only one member of the community (Grayson 1981). The validity of inferences based on the recovered vertebrate sample can be further corroborated with other associated archaeological data.

Vestígios, Revista Latino-Americana de Arqueologia Histórica

Andrés Zarankin
Departamento de Sociologia e Antropologia, Universidade Federal de Minas Gerais, Belo Horizonte, Minas Gerais, Brazil

Basic Information

Latin-American historical archaeology has been established as a field of study in the last few decades. Although the scope of research among its scholars is diverse, there are some specific issues that have attracted special attention. Among these, theoretical production and the formulation and development of alternative approaches to those produced in the centers of power can be highlighted.

Unfortunately, despite the growth and the variety of research being carried out in Latin-American historical archaeology, it still lacks the adequate amount of channels of exchange among scholars from different countries. In this sense, investigations have been restricted to the boundaries of researchers' own countries. These artificial constraints have resulted in the creation of difficulties in the search for commonalities that would allow the consolidation of a Latin-American historical archaeology.

Major Impact

It is possible to state that the establishment of connections between the archaeologies of different countries has become one of the greatest challenges being faced at the contemporary setting. The presence of pluralistic spaces of discussion is essential in approaching issues such as the genesis of modern society in Latin America and the historical connections that help to reconstruct regional social practices, in the contexts in which they occurred, through the study of material culture.

Vestígios, *Latin-American Historical Archaeology Journal*, intends to create this space of exchange and interaction among scholars of the discipline. The journal was implemented in 2007 with a solid criterion of excellence – through peer reviews – and an international board of archaeologists such as Mary Beaudry, Randall McGuire, Stanley South, Matthew Johnson, Kathleen Deagan, Pedro Funari, and Tania Andrade, among others. The journal is particularly interested in method and theory as well as in different case studies from Latin-American historical archaeology.

The journal presents two annual issues, with original papers, and the translation of a classic article (either in English or other languages) to Spanish or Portuguese (the official languages of the journal).

The journal is published by the Laboratório de Arqueologia da Faculdade de Filosofia e Ciências Humanas da Universidade Federal de Minas Gerais (Archaeological Lab of the Philosophy and Human Sciences College from the Federal University of Minas Gerais), and it has been funded by different agencies such as CNPq (Conselho Nacional de Desenvolvimento Científico e Tecnológico), FAPEMIG (Fundação de Amparo à Pesquisa do Estado de Minas Gerais), and CAPES (Coordenação de Aperfeiçoamento de Pessoal de Nível Superior).

Vestígios is available online (http://www.fafich.ufmg.br/vestigios/), free to read and download.

Veth, Peter M.

Alan N. Williams
Fenner School of Environment and Society, The Australian National University, Canberra, ACT, Australia

Basic Biographical Information

For over 30 years, the research and works of Peter Veth (Fig. 1) have become synonymous with the prehistory of the Western Desert of Australia. Along with researchers such as Prof. Mike Smith and Prof. Peter Hiscock, Peter has been at the forefront of Australian archaeological debate since the 1980s. He is probably best known for his conceptual model, *Islands in the Interior*, which explored prehistoric hunter-gatherer colonization models, the response of people to climatic fluctuations such as during the Last Glacial Maximum, and more broadly the innate dynamism and resilience of desert hunter-gatherers (see below). More recently, Peter's interests have included global models for the emergence of desert societies, colonization timing and mechanisms in Australia, exploration and analysis of rock art across the arid zone, Native Title processes and investigations, and theoretical and methodological innovations in maritime archaeology. Peter has carried out major research programs in Maluku Province (eastern Indonesia), in East Timor, and in the remote Pacific. Peter has also been heavily involved in consulting archaeology in Western Australia and other parts of Australia; he remains one of the longest serving presidents of the Australian Association of Consulting Archaeologists Inc.

Veth, Peter M., Fig. 1 Photo of Peter Veth

Peter gained an interest in the Western Desert early in his career following a 6-week survey of Sturt Creek and Lake Gregory with Charles Amsden (a Doctoral graduand of Lewis Binford). In 1982, he completed his B.A. (Hons) thesis at the University of Western Australia (UWA) focussing on quarry and open sites on the Burrup Peninsula (Murujuga). Peter's Ph.D. (and subsequent work) undertook the first systematic investigation of the Little and Great Sandy Deserts of the Western Desert. His Ph.D. thesis used both surface analysis and excavation of key sites (Yulpul, Karlamilya, Winakurinjuna, Jalpiyari) around the Durba Hills and Rudall River to explore arid zone behavior and ultimately develop the *Islands in the Interior* model. He works closely with the *Martu* peoples – the last hunter-gatherers in the world to come in to contact with Europeans as late as 1963 and 1976.

The *Islands in the Interior* model emphasized the importance of persistent water sources and the abundance of economic plant resources in piedmont/montane uplands and riverine/gorge systems as refugia in periods of climatic extremes, the three major sand-ridge deserts as barriers, and the rest of the continent as temporary barriers to occupation during the height of the Last Glacial Maximum (see Fig. 4 in the entry on "▶ Australian Deserts: Extreme Environments in Archaeology"). Despite being based on the first archaeological data retrieved from this area, this model has proved to be robust since its inception and still forms the framework for prehistoric arid zone behavior through climatic extremes today. Peter's doctoral work incorporating this model was the first Australian archaeology thesis to be published internationally (University of Michigan Ann Arbor International Monograph Series) in 1993.

Following his postdoctoral research Peter obtained a position at James Cook University (JCU) as a lecturer in 1992. Peter remained at JCU for the next 11 years, being promoted to associate professor in 1997. During this time, he implemented Australia's first maritime archaeology undergraduate stream with Flinders University (and supervised the first doctoral candidates in that discipline); shifted his research focus toward the islands of the Indonesian archipelago with Prof. Matthew Spriggs and Prof. Sue O'Connor, including the first scientific investigation of the Aru Islands and East Timor and the discovery of Pleistocene-dated shell fish hooks at Lene Hara Cave, East Timor, with Sue O'Connor; and had increasing interest across the Torres Strait Islands with Dr. Melissa Carter who discovered and dated the first prehistoric pottery in Torres Strait. Peter's interest and research, however, continued in the arid zone, and he undertook several important investigations and discoveries during this time, including his excavations (with O'Connor) at Serpent's Glen rockshelter in the Carnarvon Ranges, which still represents the earliest evidence of human occupation (>23,500 BP) in the Western Deserts; the excavations (with Mike Smith and Michael Hadley) of Kaalpi rockshelter in the Calvert Ranges allowing further investigation of late-Holocene populations in the heart of the Great Sandy Desert; and the characterization of arid coastal occupation and exploitation across the Montebello Islands off the Pilbara coastline. Here occupation has been dated to at least 30,000 years ago.

Between 2005 and 2010 Peter co-discovered the earliest occupation in the Kimberley (between 45,000 and 50,000 BP) at *Parnkupirti* on the shores of Lake Gregory and codirected the first systematic survey and investigation of the rock art, archaeology, and dreaming narratives of the 1800-km-long Canning Stock Route with Professor Jo McDonald and colleagues. He has carried out the first dating of pigment art from the arid zone of Australia with Jo McDonald and colleagues in the US.

In 2011, Peter moved back to UWA and continues to excel. He has recently been awarded the Inaugural Kimberley Foundation Ian Potter Chair in Rock Art, a Winthrop Chair; received the Australian Research Council (ARC) Discovery Outstanding Researcher Award (Professorial Level 3) – one of the first archaeologists to do so; obtained the largest ARC Discovery Project grant in Australia for the archaeological investigation of Barrow Island off the Pilbara coastline; and is the series consultant on the upcoming ABC Television series on archaeology and indigenous heritage, *First Footprints*. He is currently also the lead chief investigator of the ARC Linkage Grant *The Australian Historic Shipwreck Protection Project* focusing on the archaeological study and in situ reburial of the colonial trader Clarence (1841–1850).

Major Accomplishments

Peter's pioneering and collaborative research has addressed a number of themes in archaeology, including (a) the first global review of the archaeology of desert hunter-gatherers; (b) theorizing information exchange in the archaeology of the deserts; (c) analyzing the role of art and aggregation cycles; (d) articulating mobility models for the Pleistocene and late Holocene; (e) examining the archaeology of desert-coastal occupations; (f) critiquing Neo-Marxist and ecological models

for change in desert societies; (g) examining the adaptive role of specialized technologies in the deserts, such as the tula adze; (h) modeling for mobility and assemblage variation in the deserts; (i) progressing studies of linguistic stratigraphy and archaeology; (j) establishing early occupation of the Western Desert; (k) examining the relationship between language boundaries and art style provinces; (l) the first direct dating of pigment art in the arid zone; (m) use of ArcGIS web-enabled DBs for the management of complex and remote sites in the Western Desert; (n) the archaeology of Pleistocene hunter-gatherers on islands within the arid zone; and (o) a paradigm shift in the accepted dynamism of Australian desert hunter-gatherer societies both through time and in space. His distinguished contributions were recognized in his election as a fellow of the Australian Academy of the Humanities in 2005 and five other fellowships and major awards for research excellence since 1992.

Vicus

Harriet I. Flower
Department of Classics, Princeton University, Princeton, NJ, USA

Introduction

The study of the Roman *vicus* involves a wide-ranging consideration of local neighborhoods in both urban and rural contexts. The *vicus* defined the political, administrative, and religious subdivision of Roman settlements. At the same time, such an investigation reveals the framework, articulation, and character of local, everyday life.

Vici were the basic building blocks of the Roman community.

Definition

Vicus (plural *vici*) is a Latin term that refers to a variety of small settlements, whether in town or in the countryside, in Rome or in Roman territory, or elsewhere. It has been related to the Greek *oikos* (house), but its meaning is closer to *amphodon* (street), *kome* (village), or to the Oscan *eituns* (neighborhood). Like many Latin words, this (seemingly technical) designation has a variety of overlapping and contrasting uses. Much controversy among scholars has resulted, with the debate recently becoming more polarized. Evoking both "house" and "street," *vicus* basically refers to a group of residential buildings around a street, which can be termed a "neighborhood" or "ward" inside a city or a "village" in the countryside. The street itself is seen as a unifier of the local inhabitants and a place for their shared life.

Historical Background

In Rome, *vicus* is the most commonly used name for "street" or "lane," the alternative being *clivus*, which refers specifically to a road on a hillside ("incline"). There were only two roads called via inside the city of Rome (*Sacra* and *Nova*). We are not informed of the size of the various *vici* in Rome (although some in the countryside were certainly very modest groups of houses: Tarpin 2008). As a result, the *vicus* has often been classified as the smallest urban unit recognized by Roman administrators. The landscape of the city changed radically through time so that the number of *vici* was constantly evolving (e.g., after the great fires of 64, 69, and 80 CE).

The names of the *vici* are varied and are commonly taken from a local ethnicity (*Vicus Tuscus* "Etruscan street"), a geographical feature (*Vicus Jugarius* "Yoke street"), a locally practiced trade (*Vicus Argentarius* "Street of the Bankers"), or a local deity (*Vicus Dianae* "Diana's street"). Steinby (1993–2000) has entries for each named *vicus* we know of in Rome. The term *vicus* can often (but need not) have an administrative or judicial meaning, as is explained in a famous definition of Festus (502, 508 L with Todisco 2006), who noted the wide range of competencies enjoyed by different *vici*, especially outside town.

Vicus is a term that is related to other geographical units, notably the *pagus* ("country district"), the *mons* ("hill"), and the *regio* ("region"). However, *vici* also existed in relation to the urban fabric as a whole (*urbs*, *municipium*, *colonia*), as well as to the city's ritual boundary (*pomerium*). In some cases, such as in Imperial Rome, the *vicus* was clearly an official subdivision of a designated larger urban district (*regio*). Some information about *vici* also comes from the fragments of the early third-century CE Severan Marble Plan of Rome (http://formaurbis.stanford.edu/). During the republican period, the *vici* of Rome apparently overlapped and competed with *pagi* and *montes* in town, while their relationship to the four republican city *regiones* is not directly attested. The republican *vici* also had relationships with the voting tribes. It is notable that extant indications of addresses given in ancient texts and inscriptions nearly all cite only a *vicus* (Castrén 2000). Once you were in the neighborhood, you could easily ask for the particular house or shop you were seeking.

The *vici* were administered by officials called *vici magistri* (or *vicomagistri*), locally elected each year, who were assisted by *ministri*. These local magistrates organized the annual festival of *Compitalia*, which was the main local holiday, a movable neighborhood feast in late December or early January (eventually fixed at third to fifth of January). The *Compitalia* was celebrated with an animal sacrifice, a banquet for all, and games (*ludi*) that could include theatrical productions. On this occasion (and perhaps for other official functions), the *vicomagistri* wore the purple-bordered toga of a magistrate of the Roman people and were accompanied by a *lictor* (attendant with rods and axes). The *vicomagistri* we know of were

of humble origin, most of them being freedmen. The *ministri* were nearly all slaves.

The life of the *vici* centered around local shrines (*compita*), most often located at crossroads where two or three roads converged (Varro *de lingua latina* 6.25). These shrines, in honor of the local deities called *lares compitales*, could be simple altars or small sanctuaries according to the size and resources of the *vicus* (Marcattili 2005; Steinby 1993–2000: the few named examples bear the names of local families, unlike the *vici*). The land the shrines stood on was consecrated and marked off from its surroundings. Other gods could be added to the cult of the *lares* and would share with them in protecting the neighborhood. Meanwhile, the nature of the *lares* as deities has been hotly disputed for over a century. Their shrines received private cult on a regular (perhaps daily) basis and public recognition on the local festival of *Compitalia*. Augustus added two more public holidays for the local *lares* (Suetonius *Divus Augustus* 31).

Most scholars tend simply to equate the compital shrine with the *vicus*, thus assuming one designated shrine in each neighborhood. Such an exact equivalency is not, however, directly indicated by ancient writers, many of whom still speak of the compital shrines separately without mentioning *vici* even in the Imperial period (e.g., Pliny *HN*3.66 re. 73 CE). There has been debate about whether an official neighborhood shrine should typically have been located at the middle or on the boundary of the individual *vicus*. Some annual rituals (*lustratio*) were designed to mark off the boundaries of the *vicus* (although these boundaries are now lost to us). A *vicus* could also contain other street shrines, but these are much less amply documented than the compital shrines of the *lares*. Compital cult, practiced by Italian merchants and their households, is attested on Delos in the second century BCE, when the island was administered by Athens and, therefore, had no *vici* (Hasenohr 2003). It should be noted that the *vicus* is consistently represented as much in terms of local shrines and festivals as in terms of administration or judicial competency. At the same time, the many aspects of the *vicus* (political, religious, social, economic) were designed to affirm identity and local community, whether more or less in connection to other geographical and administrative entities.

Vici and their associated shrines could also be found in diverse patterns across Italy and in the provinces of the Western Empire (Capogrossi Colognesi 2002; Tarpin 2002). Some cities in Italy had *vici* during the republican period, presumably in imitation of Rome (e.g., Capua, Minturnae). A *vicus* outside Rome could, however, indicate either a new settlement or a local village that had been appropriated by the Roman administration or even an indigenous settlement that chose voluntarily to represent itself in Roman terms. The traditional notion that *vici* were always subdivisions of *pagi* in the countryside has recently been challenged by Stek (2009). He has argued that there was no regular hierarchical connection between these two types of administrative units and that *vici* and *pagi* were unevenly distributed across Italy during the republican period. Stek's main proposition is that the Romans spread their culture in Italy through local cults and administrative units, which were often superimposed onto older patterns of settlement and existing rural shrines.

The *vici* of Rome had a long and evolving history, as the city grew over the centuries from a handful of very modest settlements to become the dominant metropolis of the Mediterranean, with a population of over a million people (Tarpin 2002, 2008). It is possible that *vici* existed as/in the villages that predated the foundation of the city (traditional date 753 BCE). On the other hand, Dionysius of Halicarnassus (4.14.3-4, 5.2.2; writing in the early years of Augustus' principate) records a tradition that assigns the creation of *vici* and the neighborhood cult of the *lares* to (legendary) King Servius Tullius, in the context of a systematic urban reform (sixth century BCE, Pliny *HN* 36.204). While the origins of the *vici* remain obscure, they contained elements that were increasingly formalized side by side with patterns of local life that evolved organically at a grassroots level.

Key Issues/Current Debates

There has been a lively debate over more than 20 years concerning the role of the *vici* during the republican period. It has been argued that the *vici* had very little in the way of any formal administrative function before the time of Augustus (Wallace-Hadrill 2003; Fraschetti 2005). According to this argument, the subdivisions of the larger *regiones* (4 before Augustus' reform) were mainly *pagi* (with their annual festival of the *Paganalia*) and *montes* (with their annual festival of the *Septimontium*). Alternatively, the 27 shrines of the Argei may have marked the local areas of this traditional republican city (Rodríguez Almeida 2002). On this view, Augustus would appear as a truly radical reformer, who gave obscure local entities a completely new and central role in his reorganization of the city.

There is, however, ample evidence of the existence of *vici* and of their compital cults in Rome before Augustus from a variety of sources beginning in the third century BCE. Accordingly, the competing view would see republican *vici* as vital political units as early as the later third century, when local distributions of wine and oil are already attested during the war against Hannibal (Tarpin 2002; Lott 2004). The existence of the ancient Latin term *vicatim* ("by vicus" Sisenna fr. 47) provides further evidence for communication from the political center expressed explicitly in terms of *vici*. Such *vici* are thought already to have been administered by freedmen *vicomagistri* for centuries before Augustus. In other words, Augustus may merely have been systematizing a network of *vici* that had played an essential role in city administration for centuries.

The turbulent history of the *vici* in the last decades of republican government has been adduced by each side of this debate in favor of their own very distinct position. As more formal republican politics disintegrated, the *vici* emerged, both as tools of powerful popular politicians like Marius Gratidianus or Publius Clodius and as vehicles for the expression of local political sentiments, often of anger and frustration (Flambard 1977, 1981). The violence of armed groups (sometimes referred to in English as "gangs"), which drew on recruits through local networks, had become a feature of city life by the year 100 BCE. The increasingly politicized celebration of *Compitalia* grew violent and was banned in 64 BCE, then revived and banned again in the 50s BCE by the senate, and banned yet again in the 40s by Julius Caesar as dictator. Scholars have interpreted all this political ferment either as a sign that the *vici* were already official urban districts with influential local magistrates or as evidence that politics had no official role to play in the republican *vici* and was essentially subversive and unsanctioned.

The long history of *vici* in Rome was decisively shaped by the Emperor Augustus' urban reforms, which were completed in 7 BCE (Lott 2004). Augustus reorganized the city of Rome, which had outgrown the old four *regiones* of the republican city, into 14 *regiones*, of which the official subdivisions were the *vici* (Suetonius *Divus Augustus* 30). He (re)established a pattern of four annually elected *vicomagistri* and four *ministri* for each *vicus*. These neighborhood magistrates were to be (almost all) freedmen and only very few attested names are of former slaves of the Imperial household. Augustus entrusted these local magistrates with new statues of the *lares*, now called *lares Augusti* ("Augustan *lares* = August/holy *lares*"). The significance of these religious reforms has been much debated, since the nature of the *lares* themselves was under discussion by ancient writers and no ancient source gives any detailed interpretation of Augustus' innovations (Flower 2017). There is no consensus as to whether the *lares Augusti* were the same deities with new names, or quite different from the earlier *lares compitales*. Moreover, there is no evidence for *lares Augusti* outside Rome before Augustus. Regardless of precise theological definitions, Augustus clearly undertook a major initiative to restore compital shrines, renew their cults, connect them with local *vici*, and ultimately to use the resulting network to communicate directly between himself and the most humble new citizens in the local neighborhoods of Rome. Many altars and inscriptions survive as evidence for this Augustan reform (Lott 2004 has an appendix). It is not clear whether Augustus

initiated similar reforms in any other Roman city; many scholars have simply assumed this to be the case.

The *vici* marked the beginning of a new era on the first day of the new month named for the Emperor (August) in the year 7 BCE, which was to be the day when their magistrates took up their annual office. There is also evidence of Augustus giving gifts of statues of other divinities to individual *vici* from 10 BCE onward. Residents of *vici* gave small monetary offerings as gifts to the Emperor every first of January to mark the calendar New Year. The Emperor, in turn, would use this money to pay for gifts to local *vici* throughout the year. Augustus set the pattern for relationships of future Emperors with the *vici* in Rome, as is attested by the great base dedicated to the Emperor Hadrian by the *vici* of Rome in 136 CE (Tarpin 2002, R2 = *CIL* 6.31218). This inscription lists the largest number of names of *vici* known to us from any source.

In the present state of our knowledge, archaeology has only afforded glimpses of *vici*, most notably in Rome and in Pompeii (Van Andringa 2000). Meanwhile, there are real risks in combining ancient evidence from different places and time periods into any kind of general synthesis; the search for a single definition of an ideal *vicus* has tended to hamper progress.

We are on firmer ground in discussing the functions of the *vici* in Rome. The *vici* were traditionally connected to a variety of lists of inhabitants, which were kept quite separately from the official census taken by the republican censors. From early times, the *Compitalia* celebration had included the hanging of woolen dolls and balls at the crossroads, with each doll representing a free inhabitant and each ball a slave (Festus 273 L; Macrobius *Saturnalia* 1.7.34). In other words, everyone was counted. This early form of inventory was supplemented by the lists of local inhabitants kept by owners of buildings, which may also have been posted. Such lists of local people were used as the basis of *vicatim* distributions of goods. The distribution of grain, whether free or at subsidized prices, was initiated by Gaius Gracchus in 121 BCE and evolved over time into a regular system. Julius Caesar initiated a new type of census based on the local *vici* (Lo Cascio 2008). This network of local knowledge was used to constitute what became a privileged class, known as the *plebs frumentaria* ("the people entitled to the grain dole"). In this way, the *vici* served as the basis for the grain dole, even as the list of recipients came to be identified as the true Roman people (Virlouvet 2009).

Similarly, the provision of drinking water at public fountains, protection against fires, and local law and order in the streets were all delegated, at their lowest level, to responsible parties in the *vici*. Augustus continued to draw on this local expertise and manpower, even as he introduced greater systemization into each of these administrative areas. In 6 CE, the *vigiles*, a large professional fire brigade composed of freedmen, was established in separate barracks throughout the city (Sablayrolles 1996). In a Mediterranean urban landscape in which shops and businesses tended to congregate by type in the same geographical area, the local *vicus* will often have had its own economic character. At the same time, each area of the city contained small businesses that catered to local daily needs.

Housing in Rome (as in Pompeii and elsewhere) seems to have been very mixed. There were exclusive neighborhoods, as well as poor ones, but most city streets will have had a wide variety of inhabitants who lived locally and who could be seen walking around on the streets, since vehicular traffic was generally prohibited in town during daylight hours. Many inhabitants of Rome were slaves, at least for some part of their lives. Many others had connections or property in the countryside and were only in town for a few years or at certain seasons of each year. Rome also attracted many foreigners. A study of the *vici* involves the demography of the local population, which was constantly in flux because of high rates of mortality, movement, and the manumission of slaves.

The rhythms of daily life, at the water fountain, the small bakery, the neighborhood shrine, and the local workshop, could be found in each *vicus*. It was here that news or views were exchanged and violence or self-defense could be planned. Consequently, the political élites sought out the locals in

their neighborhoods, to influence or patronize their humblest neighbors, even as the *vici* could generate an expression of local political opinion. In a huge city without a formal police force, the *vici* were the basic units that made urban life possible. Even after the Emperor Tiberius built a barracks for the Praetorian Guard in Rome, everyday security still depended on local oversight. Augustus used a network of renewed *vici* to establish himself as Rome's leader in relation to ordinary people. He did this not for merely administrative reasons but because the *vicus* signified "home" for poorer Romans.

International Perspectives

Since the precise definition of a Roman *vicus* is still hotly debated, comparisons with urban patterns in other cultures have proved elusive. The question of size is clearly of central importance. Scholars who see the *vici* of Rome as large are, therefore, more likely to compare them to substantial urban units, such as the ward or district. By contrast, the smaller *vicus* suggests a localized neighborhood on an individual street. In the latter case, a comparison with the traditional Chinese *hu-tong*, especially in Beijing, is suggestive but has not been explored in any detail so far. A *hu-tong* is a narrow road lined with traditional courtyard houses, local shops, and bathing establishments (Meyer 2008). Such small streets are still to be found in Beijing but have mostly lost their local shrines and traditional religious culture as a result of more than 60 years of communist rule.

Future Directions

The best way to move forward with the study of *vici* would be through systematic and scientifically sophisticated archaeological excavation. The exploration of an unexcavated streetscape in Pompeii would provide the most promising opportunity. In Rome, a renewed focus on streets and neighborhoods would also be desirable, although much more difficult in practice. In the country, rural *vici* will emerge through more general surveys of larger areas of settlement and religious centers of local importance.

Vietnam's Archaeological World Heritage Sites

Nam C. Kim[1] and Hiep Hoang Trinh[2]
[1]Department of Anthropology, University of Wisconsin-Madison, Madison, WI, USA
[2]Institute of Archaeology, Vietnam Academy of Social Sciences (VASS), Hanoi, Vietnam

Introduction

Archaeological research in Vietnam has a long and rich history, formally commencing during the French colonial period and continuing through today, and the country's archaeological record extends into the Paleolithic (Higham 2002). Today, archaeological projects in the country are executed through the Institute of Archaeology, which is part of the Vietnam Academy of Social Sciences. It is generally a nationally sponsored research enterprise. Much of the field research in recent decades has served to broaden our understanding of various historically significant sites in Vietnam, which has in turn had an impact on their designation as UNESCO World Heritage sites.

Stewardship of many archaeological sites, especially those with a high international profile, involves a mixture of national and local involvement. The Socialist Republic of Vietnam ("Vietnam") ratified the World Heritage Convention in 1987. Currently, Vietnam has seven properties inscribed as World Heritage sites, consisting of two natural heritage and five cultural heritage sites. Vietnam's "Law on Heritage," formulated in 2001, covers all elements of heritage classification, controls archaeological excavation, outlines preservation activities, and also addresses sustainable tourism. Management of each site is largely under the direction of the government, specifically the Ministry of Culture, Sports and Tourism (founded in 2007), with the involvement of various national and local administrative units and offices. The new ministry is the merger of former committees and ministries, including the former National Sports Committee, the National Administration of Tourism, and the former Ministry of Culture and Information. Prior to the merger, all of Vietnam's World Heritage activities were overseen by the Ministry of Culture and Information (Di Giovine 2009: 216). While the headquarters are located in Hanoi, satellite offices are located in most cities and at every World Heritage site (Di Giovine 2009: 216). Between 1995 and 2005, the number of tourist visits to Vietnam and its World Heritage sites increased from 1,351,000 to 2,972,000 at an annual rate of 9.2% (Di Giovine 2009: 4).

Key Issues/Current Debates/Future Directions/Examples

World Heritage Natural Sites

Hạ Long Bay
Property: 150,000 ha

Ha Long Bay ("Descending Dragon Bay"; Vietnamese: *Vinh Ha Long*) is situated in the Gulf of Tonkin and features a remarkable seascape of islands and limestone pillars. Most of the islands

are uninhabited, though archaeological sites such as Cai Beo on the island of Cat Ba have been found (Higham 2002: 36). It is a popular domestic and international tourist destination, located in the Quang Ninh province. The Hạ Long Bay site is overseen and managed by the Hạ Long Bay Management Board of Quảng Ninh People's Committee. Administratively, the bay belongs to Hạ Long City, Cam Pha town, and is part of the Van Don District. Featuring thousands of limestone karsts and isles in various sizes and shapes, Hạ Long Bay is the center of a larger zone which includes Bai Tu Long Bay to the northeast, and the Cat Ba islands to the southwest.

The bay's geomorphology is known as a drowned karst landscape due to the unusual combination of its limestone karst features. One distinctive feature of Ha Long Bay is an abundance of lakes within the larger limestone islands. Additionally, extensive limestone caves represent another important feature. In all, Ha Long Bay possesses a tremendous diversity of caves and other landforms.

The property's extent includes 1,960 islets, most of which are limestone, and the bay is home to 14 endemic floral species and 60 endemic faunal species. The core zone of Ha Long Bay was listed by UNESCO as a World Heritage site in 1994, with an extension granted in 2000.

Phong Nha–Ke Bang National Park

Property: 85,754 ha

The Phong Nha–Ke Bang National Park (Vietnamese: *Vuon quoc gia Phong Nha – Ke Bang*) is in the Bo Trach and Minh Hoa districts of central Quang Bình Province, in north-central Vietnam, about 500 km south of Hanoi. The Phong Nha Nature Reserve is situated on the edge of the Phong Nha/Ke Bang Karst plateau, and the plateau extends into Laos.

The park derives its name from both Phong Nha cave and the Ke Bang forest. The park was created to protect one of the world's two largest karsts regions with 300 caves and grottoes. Noted for its spectacular and extensive cave and grotto systems, the area is comprised of 300 caves and grottoes, of which only 20 have been surveyed by Vietnamese and British scientists. In April 2009, the total length of the caves and grottoes was extended to 126 km after the discovery of the Son Doong Cave.

Some of the caves have yielded archaeological evidence for early Holocene occupation, while other caves and grottoes show signs of use within the past millennium.

This national park was inscribed as a World Heritage site in 2003. The park is overseen and managed by the National Park Management Phong Nha–Ke Bang of People's Committee of Quang Bình Province.

World Heritage Culture Sites

Complex of Hue Monuments

The complex is located in the Thua Thien Province of central Vietnam. Hue represents a past Vietnamese feudal empire at its apogee during the early nineteenth century. Hue served as the administrative center of southern Vietnam in the seventeenth and eighteenth centuries. The Nguyen dynasty made it the national capital of a united Vietnam in 1802, a position held by the site until 1945. The Perfume River divides the capital in two. A total of four citadels or defended enclosures made up the city: Kinh Thanh (Capital City), for official administrative buildings; Hoang Thanh (Imperial City), for royal palaces and shrines; Tu Cam Thanh (Forbidden Purple City), for the royal residences; Dai Noi (or Inner City); and Tran Binh Dai, an additional defensive work in the northeast corner of the Capital City, designed to control movement on the river. A fifth fortress, Tran Hai Thanh, was constructed a little later to protect the capital against assault from the sea. At the heart of the complex was the Forbidden Purple City, enclosed by brick walls. Originally, there were over 40 buildings within the enclosed area, but most are now in disrepair.

The complex suffered considerable damage due to military conflict in 1885, 1947, and 1968. Due to its historical significance, Huee was inscribed as a cultural heritage site by UNESCO in 1993, and is managed by the Hue Monuments Conservation Center (HMCC) and the Hue People's Committee.

Hoi An (Ancient Town)
Property: 30 ha
Buffer zone: 280 ha

Hoi An is an ancient town located in the lower section of Thu Bon River, the coastal plain of Quang Nam in Central Vietnam. It is an exceptionally well-preserved example of a traditional Asian trading port and maritime commercial center. Most of the buildings are in the traditional architectural styles of the seventeenth to nineteenth centuries, and they include religious buildings such as pagodas and temples. The town is considered to be something of a living museum of architecture and urban lifestyle. Many festivals occur at Hoi An annually, preserving traditional lifestyles, religious ceremonies, customs, and culinary practices. Due to its geographic position, Hoi An was an active international trading port for traffic of merchant ships from Japan, China, and the Western world during the seventeenth and eighteenth centuries.

The current architecture of Hoi An, almost exclusively in wood, combines traditional Vietnamese designs and techniques with those from other countries, such as China and Japan. Reminiscent of Japanese examples, there is a wooden bridge with a pagoda atop it. An inscription indicates it has existed from at least the early eighteenth century. There are also numerous ancient tombs in Vietnamese, Japanese, and Chinese styles.

Archaeological finds and excavations have shown this area to have been an active port and trading center since the Iron Age Sa Huynh people lived in the area, along the Thu Bon River as early as the second century BCE. The ancient town is situated on the north bank of Thu Bon River, and continued to operate as an important port of Champa civilization. At the epicenter of ancient Champa civilization, Hoi An became one of the most important port cities, a designation that would last for several centuries (Di Giovine 2009: 262).

Starting in the 1980s, the architecture and culture of the Hoi An ancient town gained increasing scholarly and tourist recognition and interest, making it one of the major tourist attractions of Vietnam. Today, most if not all of the homes within the historic center of Hoi An have been restored according to international preservation standards, and most of its residents are actively engaged in the tourist industry (Di Giovine 2009: 265).

The site is managed by the Conservation Management Center for the Relics of Hoi An and the People's Committee of the Quang Nam Province. In 1999, the property was inscribed as a World Heritage site.

My Son Sanctuary
Property: 142 ha
Buffer zone: 920 ha.

Located in the Duy Xuyen district of the Quang Nam Province of central Vietnam, the My Son sanctuary is 45 km west of Hoi An and 70 km south of Da Nang. This sanctuary area is known as the most significant Champa architectural and sculptural monuments in the country.

A valley surrounded by mountains, My Son was the site for a religious center for the capital of the Champa Kingdom. The site is an important example of ancient and historical cultural exchange, with the introduction of the Hindu architecture of the Indian subcontinent into southeast Asia. At the start of the first millennium, the Champa civilization increasingly came under the influence of Hinduism, and many Hindu temples were subsequently built. Successive kings in the sixth to eighth centuries continued to construct temples and monuments. Warfare during the medieval period affected the site, leading to the decline of Champa civilization and its eventual absorption into the Dai Viet state in the fifteenth century.

My Son consists of eight groups of tower temples cover a period from the tenth to the thirteenth centuries, and this chronology is reflected in different architectural styles. The temples are constructed in fired brick with stone pillars and decorated with sandstone bas-reliefs depicting scenes from Hindu mythology. The major style of architecture and sculptural motifs derives directly from Indian civilization.

Conflict in the twentieth century also damaged many of the structures at My Son. During the

1960s, My Son periodically functioned as a military base and mines were set on the hillsides and the mountain slopes. Devastation occurred due to heavy bombing by the USA in August 1969, during which many of the temple-towers were severely damaged. Only approximately 20 temple-towers still remain intact. However, most of the surviving inscriptions and archaeological materials are preserved and held in My Son and in various museums.

My Son was inscribed as a UNESCO World Heritage site in 1999, along with Hoi An. It is home to hundreds of thousands of tourists and researchers annually, and the site is managed by the Conservation Management Center for the Relics of My Son and the People's Committee of the Quang Nam Province.

Central Sector of the Imperial Citadel of Thang Long

Property: 18 ha
Buffer zone: 108 ha

Thang Long – Hanoi Imperial Citadel (Vietnamese: *Hoang thanh Thang Long*) refers to a cultural complex located in the heart of modern-day Hanoi, and its traces were recently uncovered during construction of new buildings in 2002. The site at 18 Hoang Dieu Street was chosen for the construction of the National Assembly, but development stopped when traces of the Imperial Citadel were uncovered.

Originally, the Imperial Citadel was first built in the eleventh century by the Ly Dynasty, marking the independence of the Dai Viet kingdom after a millennium of Chinese colonial rule. It was constructed on the remains of a Chinese fortress on drained land reclaimed from the Red River Delta in Hanoi. The site would remain the center of uninterrupted regional political power for the next several centuries. The Citadel enclosed the Forbidden City, constructed in brick in the eleventh century, and was itself enclosed by a defensive wall.

The Citadel reached its apogee in size in the sixteenth to seventeenth centuries. French colonial control of Vietnam began in the 1880s, and Thang Long functioned as the colonial headquarters for French administration of Indochina (modern Vietnam, Laos, and Cambodia). The royal palaces and many structures were destroyed in the late nineteenth century. Several palaces and historic buildings were rebuilt according to a French architectural style. After the First War of Independence (1954) and the division of Vietnam into two entities, the ancient Forbidden City became the military headquarters for North Vietnam. The Ministry of Defense gradually abandoned its use of the property between 1994 and 2004, designating it for cultural and historic purposes.

Due to its historical significance and location within the modern capital of Vietnam, the management of the site is quite complex and has increasingly involved multinational participation. The site is directly managed by the Conservation Center for the Co Loa and Hanoi Citadels (also known as the Hanoi Ancient Wall–Co Loa Vestiges Preservation Center). The Center was established in 2007, and has approximately 100 staff members. In addition to overseeing the Thang Long Citadel (also known as the Hanoi Citadel), the Center also manages the nearby Co Loa site. The Center is overseen and funded by the Hanoi People's Committee, the Ministry of Culture, Sports and Tourism, as well as the Vietnam National Commission for UNESCO. The Center cooperates with the Vietnam Institute of Archaeology (which is part of the Vietnam Academy of Social Sciences).

The central sector of the Imperial Citadel of Thang Long was inscribed as a World Heritage site in June 2010. In October 2010, UNESCO Director-General Irina Bokova made her first official visit to the country and, coinciding with Hanoi's Millennial Anniversary Celebrations, handed over the World Heritage certificate to government officials. Following a request from the Vietnamese government, UNESCO is supporting the Vietnam National Commission and the Hanoi People's Committee to ensure Thang Long's long-term conservation. With technical support from the Tokyo-based National Research Institute for Cultural Properties, the Vietnamese Ministry of Culture, Sports and Tourism, the Conservation Center for the Co Loa and Hanoi Citadels, the

Vietnamese Academy of Social Sciences (VASS), the Institute of Vietnamese Studies and Development Sciences (IVIDES), and the Institute of Monument Conservation, a comprehensive site management plan for the complex is being developed and implemented to ensure the long-term conservation and sustainable development of the site (Regional Committee of Tourism Paris Ile-de-France 2008). As part of this effort, a focus will be placed on local capacities for site managers, planners, and research scientists.

Citadel of the Ho Dynasty

Property: 156 ha
Buffer zone: 5,079 ha

The Ho Citadel (Vietnamese: *Thanh nha Ho*) (Fig. 1) is located in the Thanh Hoa Province in Vietnam's north-central coast region, approximately 150 km south of Hanoi. It was the capital of Vietnam from 1397 to 1407 during the short-lived Ho Dynasty.

Measuring 877 × 889 m, the citadel is marked by an enclosing wall of stone, which still remains standing. The enclosure has a diameter of over 3,500 m, with a wall height of 5–6 m. Unlike other citadels in the country that were constructed with brick, construction of the Ho Citadel employed massive stone slabs sourced from nearby mountains. The stone materials used for construction were carefully hewn into slabs with uniform dimensions, and the citadel was marked by four arched gates (south, north, east, and west). Researchers are currently exploring how the stone walls were constructed. According to historical texts, construction was

South gate

North gate

Vietnam's Archaeological World Heritage Sites, Fig. 1 (continued)

East gate

West gate

Vietnam's Archaeological World Heritage Sites, Fig. 1 The gates of the Ho Citadel (Source: Vietnam Institute of Archaeology)

completed in 3 months, seeing the transport and erection of over 25,000 cu m of rock, averaging 10–20 tons per slab (Tong Trung Tin, *pers. comm.*).

The Citadel was inscribed as Vietnam's seventh World Heritage site in June 2011. Approximately 1 month after inscription, a quarry was identified 2 km northwest of the site that may be the source of the stone materials. Researchers from the Ho Dynasty Citadel's Heritage Preservation Center have discovered 21 flagstones scattered across a wide area. Based on clues such as cutting marks on the surface of the stones and comparisons with slabs from the citadel, the

researchers speculate that the stones were intended for use at the Citadel but were discarded due to faults. A multiyear excavation project is planned at the quarry site.

The site is managed by the Ho Dynasty Citadel's Heritage Preservation Center in conjunction with the People's Committee of Thanh Hoa and the Ministry of Culture, Sports and Tourism.

Future Directions

The state-sponsored Institute of Archaeology, headquartered in Hanoi, employs hundreds of archaeologists working throughout the country on projects ranging from the Paleolithic to protohistoric and historic eras. Given the volume of archaeological fieldwork, the pace of research, and the number of sites within the country, it is likely that Vietnam's list of World Heritage properties will continue to grow in the coming years. To illustrate, as of this writing, there are currently seven additional properties being considered on the UNESCO Tentative List.

Villas and Farms in the Mediterranean World

Annalisa Marzano
Department of Classics, University of Reading, Reading, UK

Introduction

Farms and villas were ubiquitous in the regions of the ancient Mediterranean. Ancient villas were mansions located outside urban agglomerations including residential quarters displaying a complex architectural and decorative vocabulary and facilities for the processing and storing of agricultural crops. They are usually discussed mostly in the context of the history of architecture, of agricultural exploitation, or of type of management and labor of ancient Classical Greece and Rome, but farms and the so-called proto-villas actually predated the Classical Greek period and are attested in the Etruscan and Punic worlds as well. However, the Greek Classical period and, to a greater extent, the Hellenistic period were defining moments in terms of the delineation of clearer architectural typologies and a more regular diffusion of these dispersed settlements in the countryside. In the Hellenistic period, the number of villas and farms populating the countryside of areas such as mainland Greece, peninsular Italy, and Sicily greatly increased. Both in Rome and in ancient Greece, where the social and political structures were based on census, landed wealth was the criterion determining the belonging to one class or the other. Minimum landownership was therefore what qualified one as a citizen soldier, and for this reason,

landownership, i.e., farms and villas, is indissolubly linked with ancient states' social and political history.

Definition

Villas are categorized into three types, using Latin terminology: (1) *villae suburbanae* (suburban villas), located in close proximity of towns and cities; (2) *villae rusticae* (rural villas), located in the countryside, which could be the management center of large agricultural estates (*latifundia*); and (3) *villae maritimae* (maritime villas), located on the seacoast or also on lakeshores. Some scholars make a further distinction between maritime villas (with structures built right on the shore, such as fishponds and bath complexes) and coastal villas, located on the coastline but not having a direct relationship between their architecture and the sea (Lafon 2001).

Villas usually featured a single compact structure with a central courtyard, which functioned as a connecting element between the different parts. A villa would, in general, consist of (a) *pars urbana*, the part where the owner and his family would live; (b) *pars rustica*, the place where the productive activities of the villa took place, including also the living quarters of the staff and slaves, as well as the farm animals; and (c) *pars fructuaria*, where the products were stored. The villa of Settefinestre near ancient Cosa, Italy, exemplifies this organization of space well.

Ancient literary sources stress that maritime villas, unlike their rural counterparts, were unproductive, a manifestation of elite conspicuous consumption. When maritime villas have been more extensively excavated, however, the presence of a *pars rustica* or of other production activities have often been found. Indeed, all natural resources of the villa estate may have been exploited, e.g., clay beds, quarries, and lagoons (for fishing, fowling, etc.). Maritime villas were often the seat of a particular type of production, *pastio villatica*, i.e., the production of quality foods for the urban market which comprised such things as honey, fish, and game.

For the Romans, the term "villa" could convey a variety of meanings; it was commonly used to refer either to farms or to the opulent country mansions of the elite. A key defining factor, however, was the location outside the urban context, as legal sources make clear. Reading the ancient texts, it is also clear that "villa" indicated different things to different authors at different times. Significantly, Varro, the first-century BCE author of a treatise on agriculture in the form of dialogue addressed to the Roman upper class, starts his work with a discussion over the meaning of "villa" which shows the range of meanings covered by the term in his time. By the late fourth century CE, "villa" no longer indicated the landed estate but the settlement and the land held by several owners, in other words a village (Bowes and Gutteridge 2005).

The elements marking the distinction between farm and villa are size and degree of refinement of the décor. As a very general rule, in a farm the ratio between residential rooms and service spaces is no more than 1:3 of the total area, whereas in villas, the residential part was much larger and more richly decorated. Also in the case of farms, a central courtyard was the main architectural feature; the number of rooms varied depending on the size of the farm. Villa Regina (Boscoreale, Italy) is a good example of a large farm featuring a wine press, threshing floor, and moderate architectural décor. Often, though, the building technique employed in farms was wattle and daub on stone foundations, and the building would consist of a few rooms only. Since excavations have mostly focused on large and, architecturally, more visible buildings, excavated farm buildings are small in number. Therefore, the knowledge about the presence of farms and the chronology in a given territory comes largely from field survey.

Historical Background

Villas and farms were the characterizing elements of the landscape of the Hellenistic and Roman Mediterranean. Considered to be the indication of a particular type of exploitation of the land,

featuring on the whole polyculture but with pre-eminence given to cultivation of vines, olive trees, and fruit trees essentially aiming at the production of surplus for the market, the diffusion of villas and farms can be traced in certain geographic areas alongside states' territorial expansion. In northern Greece, the growth of the Macedonian kingdom in the Hellenistic period facilitated in some areas the creation of large estates which appear to have promoted the introduction of new technologies in order to process crops more efficiently, as in the case of the olive rotary crusher (Foxhall 2007). In Italy, during the third century BCE, farms started appearing in greater densities in the territories conquered by Rome. The South Etruria Survey has recorded thousands of rural settlements comprising farmsteads, farms, and villas. While the exact chronology of occupation of these sites can only be partially determined in field survey, for one is dependent on only the artifacts visible on the ground and on their quality as chronological markers, it was nonetheless possible to define a broad chronological development which indicated increased number of sites in the archaic period and in the second to first century BCE, a massive peak in the first and second century CE, with decrease in number of sites starting in the late second/third century CE (Di Giuseppe 2005).

The "standard history" of the evolution of farms and villas in Roman Italy put forward by the historiography of the 1970s and 1980s has been characterized by an evolutionist model (Terrenato 2001): small farms appeared in the third century BCE as the result of the Roman conquest; during the second century BCE in the aftermath of the Hannibalic war, which opened the way to Rome's conquests in the East, some developed into villas. The availability of manpower (slaves) and riches that the conquering wars brought about allowed the elite to create slave-staffed villas producing cash crops. The landed estates of the wealthy grew in size, incorporating former small- and medium-sized properties and large tracts of *ager publicus*. The displaced small farmers ended up swelling the ranks of the urban *plebs* in Rome, starting the Gracchan movement for land reforms, the subsequent profound transformation of the army, and the crisis of republican institutions. In fact, data from field surveys carried out across different regions of the Italian peninsula indicate that there was no exclusive relationship between farms and villas. Rather than seeing the former decrease when the latter increase in number, the two seemed to have increased or decreased together (Launaro 2011).

Since the appearance of farms and villas in the territories conquered by Rome is considered a typical Roman way of exploitation of the land, an issue that has interested scholars has been to determine what the origins of the "villa," both in its architectural typology and types of production, were. Farms and villas engaged mostly in producing wine and olive oil were present in the Greek Classical and Hellenistic world, and some have linked the appearance of villas in the Roman world in the third century BCE to the contacts with the southern part of the Italian peninsula and its Greek colonies (Lafon 2001). Others have preferred to stress a link with the Punic world of North Africa. Carthage, before its destruction by Rome in 146 BCE, was surrounded by many farms and villas. The wealth of the city came as much from her agricultural hinterland as from the extensive Mediterranean commercial networks. Although archaeological excavations of Hellenistic Punic farms around Carthage are scant (Brun 2004), it is known that courtyard villas fortified by corner towers were in use both in Sicily and in North Africa as early as the third century BCE. Roman authors, such as Appian (*Pun*. 101; 107), normally refer to Punic farms as *turres* (towers) or *castella* (fortified buildings), stressing their fortified nature. Recent discoveries on the island of Jerba, off the cost of Tunisia, have highlighted the great diffusion in the Hellenistic period of villas producing sweet wine which was widely exported around the Mediterranean (Fentress 2001). In addition, arboriculture and certain cultivations that later characterized the production of Roman villas seem to have been developed to a greater extent in the farms of Carthage. The agricultural treatise by the

Carthaginian Mago was judged by the Roman senate in 146 BCE to be the only noteworthy work deserving to be translated into Latin. Agricultural manuals written later by Latin authors, in particular Varro's and Columella's (first century CE), often quote Mago's work as a source.

Fortification of rural dwellings was a feature not limited to the Punic world of North Africa and Sicily. Mainland and insular Greece offer several examples of rural stone towers dating to the Classical and Hellenistic period, at times part of farms and at times more isolated. These structures, for a long time seen exclusively as serving defensive needs, have recently been connected to the productive exploitation of the Greek landscape and to the dependent labor that enabled these activities, since they might have confined unfree labor engaged in agriculture and mining activities on estates of absentee wealthy owners or tenants (Morris and Papadopoulos 2005).

The two alternative models for the origin of the villa, the Greek or the Punic worlds, have been questioned after the important archaeological discovery of the Auditorium Villa in Rome in the late 1990s. Here, a substantial villa existed already in the years 500–300 BCE; further enlargement of the complex occurred in 300–225 BCE. The name "villa" for this archaic and early republican complex is justified primarily by its size, so far unparalleled for the same period; by the décor (see the figurative architectural terra-cottas of the second phase, similar to those known from Etruscan religious buildings); by the type of plan, featuring a central open court; and by the presence of an oil press (Carandini 2006). The complex had a long occupation history, going out of use after the mid-second century CE. This discovery has led to the reconsideration of finds at other later villa sites, where the recovery of archaic architectural terra-cottas had been explained with abandoned archaic rural sanctuaries which later had been obliterated by the construction of farms and villas. Instead, it has been proposed that these might constitute similar cases as that of the Auditorium Villa: palatial rural structures typical of the Etruscan world, from which the Roman villa evolved (Terrenato 2001). Indeed, one does not need to wait until Rome's territorial expansion in the third century BCE to see indications of the intensification of agricultural exploitation in its environs, especially in the case of viticulture. At various sites in the southeastern *Suburbium* near modern Centocelle, wherein the late republic and empire luxurious villas were built, archaeological investigations have revealed numerous trenches dug in the tufa plateau in order to plant vines, dated on the basis of associated ceramic material to the fifth century BCE. The intensification of settlements in the countryside for agricultural purposes resulted in at times massive interventions to make the land suitable to cultivation. In order to develop the marshy Fondi plain for viticulture in the second century BCE, thousands of amphorae were laid head to toe in order to drain the land. In this area, several farms and villas were built starting in this period.

Architectural Typology

From an architectural point of view, it is possible to identify changes in villa architectural typology that mark specific chronological periods. The second century BCE marked a transition in villa architecture in Italy, with the incorporation of elements typical of the townhouse into the plan of typical villas, such as the atrium and the peristyle garden. These architectural elements had no direct practical function in relation to agriculture but added monumentality to the residential quarters. Together with the degree of lavishness in furnishings – statuary, mosaics, and wall paintings – these architectural elements became the indicators of the wealth and social status of the owner and, at the same time, a "must-have" feature if one had aspirations to become part of a socially higher group. Generally speaking, the republican villa was built on imposing substructures housing cisterns (the *basis villae*), creating at least two artificial terraces. On the upper one was the villa building; on the lower were gardens and orchards. The Villa Prato near Sperlonga is a good example of the use of two terraces and of the simple division between residential quarters on one side and service area with two presses on the other (Broise and Lafon 2001). Although the bath quarter excavated at this villa is unusual in typology and early chronology, small bath suites

appear regularly in residential quarters of villas up to the early first century CE. These facilities are always located in proximity to the kitchen, a practical planning solution which facilitated the heating of the water for the baths and rationalized the drainage and water supply lines, grouping together the rooms (kitchen, baths, latrine) that needed them. In late republican and early imperial villas, the atrium and peristyle court were often enlarged, while one or more rooms opening onto the peristyle, used for dining and other reception activities, were added. Other changes notable in the period regarded not only the architecture but also the décor. For flooring, earlier examples of *opus signinum* floor with a decorative pattern made with the insertion of pebbles give the way to mosaics and marble tile floors (*opus sectile*).

In maritime villas, also built on various levels and in very scenic positions, the residential quarter was placed on the seaward side, while the service quarters were on the mainland side. Architectural elements that were exploited to great extent in Roman villa architecture starting from the Augustan period were the portico and the cryptoportico. The use of the colonnaded portico in particular represents the assimilation in the private sphere of an element typical of Hellenistic and Roman public architecture. Portico and cryptoportico were used by villa designers as key elements in determining the circulation space and in providing socially distinct access to the villa's parts (Zarmakoupi 2011, 2014).

The late first century CE and early to mid-second century CE mark a change in villa typology. Residential quarters become larger and more elaborated; peristyle courts and gardens are replicated, as are dining rooms and reception areas. In the second century, bath quarters featuring the canonical sequence and layout of rooms (*frigidarium*, *tepidarium*, *caldarium*) observable in the large urban baths appear, often as independent pavilions rather than as part of the central body of the villa. Other architectural features that characterize second-century large villas are large gardens framed by colonnaded porticoes, often with decorative water features, monumental *nymphaea*, and the so-called garden-stadia, i.e., walled gardens in the shape of an ancient stadium.

The suburban villas around Rome continued to flourish and to become more opulent until the late antique period. In other regions, different trends are observable; for instance, luxury villas around Ravenna and in the lake region in northern Italy appeared only when the imperial seat was moved to Milan first (286–402 CE) and to Ravenna later (402–476 CE). Late antique villas present at least one large reception hall and larger dining rooms no longer accommodating the typical set of three couches, each able to accommodate three diners, which were placed to form a U along three sides of a rectangular room, but the *stibadium* is found instead. The *stibadium* was a semicircular dining couch; one or more could be accommodated in a late antique dining hall, which normally featured at least one apse along one wall but could have up to three apses (*trichonch*). The apse is indeed the defining element of late antique architecture. The ultimate example of a late antique villa is the Villa Casale at Piazza Armerina in central Sicily. The scale and opulence of this complex are such that it is still debated whether it was in fact an imperial palace, the palace of a governor, or "simply" the villa of some powerful member of the elite.

Another element that characterizes architecturally the late antique villa is the presence of mausolea or of monumental tombs within the villa building. Whereas in previous periods, monumental tombs were built on the villa estate, in isolated prominent positions visible from a major road that passed nearby, in late antiquity, the mausolea appear as part of the villa architecture. It has been suggested that such cases reflect the diffusion of Christianity and martyr cults. Augustine in the *De Civitate Dei* (22.8) lists many miracles, which took place at villa martyr shrines. In fact, tying a Christian ritual space to a functioning villa is problematic. Even when early churches are often built near or on top ruins of abandoned villas, to what extent the villa acted as a point of memory for the development of Christian worship and to what extent location was simply determined by the fact that the villa offered readily available building material are not clear.

The development of architecturally magnificent villas was a phenomenon not limited to Italy and the environs of Rome. Provinces where

the local and the senatorial aristocracy of Rome established estates at a significant level, such as Epirus, Dalmatia, Hispania, and North Africa, all have examples of monumental villas. These structures developed alongside the occupation of marginal lands by farms. Especially in North Africa, the Roman period is characterized by farms and complex irrigation systems bringing under cultivation marginal lands which in earlier and later epochs were not cultivated.

A region which displays particularly fine examples of villa complexes built in the imperial period on a monumental scale is Istria (Croatia). During the first century CE, particularly on the western coast, several grand villas were built; epigraphic evidence indicates that much of this area was under ownership of Rome's senatorial elite (Tassaux 2003). These estates produced wine, olive oil, and also purple dye. The most impressive example of Istrian villas is the Verige Bay villa, on the island of Veli Brijun in the Adriatic Sea. At the height of its development, it featured three templelike structures linked by a semicircular portico, an outdoor apsidal dining area at the end of a ca. 150-m long colonnaded area, a bath complex and an adjacent garden, and a major residential quarter unfolding around a peristyle in the main block. One sector of this huge complex was devoted to the processing of olive oil, revealing what type of cultivation was prevalent on this estate (Schrunk and Begović 2000).

Key Issues/Current Debates

Four main issues can be identified in the context of current debates on villas and farms:

1. Recent archaeological and historical studies have been reconsidering the traditional view that Rome's social crisis, centered around issues of land distribution which occurred from the second century BCE onward, was due to the growth of large slave-staffed villas which displaced small- and medium-sized farmers. Field surveys accompanying the excavation at the villa of Settefinestre had indicated that in this area there were few farms when this villa flourished, thus seemingly confirming ancient texts referring, for south Etruria, to a countryside depopulated of free farmers, instead occupied only by large slave-staffed estates. More recent work has on the contrary observed that this phenomenon cannot be generalized, since in many areas of Roman Italy, small- and medium-sized farms continued to exist well into the imperial period. Whether these farms were part of larger estates belonging to the wealthy and were rented out under a sharecropping system or whether they were owned by small proprietors cannot be determined from a purely archaeological point of view. The fact that small farmers were able to be competitive on the market in terms of production has also been pointed out (Kron 2008).
2. After the Roman conquest of Gaul and the Spanish provinces, land distributions and the foundation of colonies occurred in several areas of these provinces in the late first century BCE and early first century CE. On the land plots, the colonists built farms and planted vines. Until then, these regions had been large importers of wine from Italy, but soon, the production of these farms started to replace Italic wine both on regional and transmarine markets. By the Flavian period (69–96 CE), the farms were enlarged into villas, equipped with a well-appointed residential part and service areas, indicating that the successful wine business allowed now the owners to spend on the beautification of their residences (Brun 2005). In Italy, at several villa sites in the second century CE, the subdivision of rooms into smaller units, poor-quality repairs, and even burials placed within the former residential part of the villa were observed. These two phenomena were linked, positing that estates that had been producing wine for export had been affected by the new provincial production and that owners had, in effect, abandoned them; the poor repairs and the burials were, in this scenario, the signs of squatters. When all the available evidence is considered, however, it appears that signs of demise at villa sites do not coincide also with the abandonment of cultivation. The concentration of land in the

hands of fewer proprietors led some owners to keep fewer villas equipped with adequate residential quarters for their sojourns, leaving the others to the use of their tenants (Marzano 2007).

3. Despite the apparently straightforward nature of defining what a farm is, from the point of view of archaeological classification, what constitutes a farm is, partly, debated. When looking at excavated structures, it is disputed whether a temporary residence should be called a farm or only a permanent one and whether a distinction should be made between farming and herding (we might think of structures related to transhumance, occupied only seasonally, for instance). In the context of field survey, scholars have been asking whether a sherd scatter in a field necessarily constitutes a farm or whether it only attests to the ancient agricultural practice of manuring. If a sherd scatter always defines a farm, what scatter size indicates this type of dwellings, and what scatter size indicates a "villa?" It is known that, over time, especially in fields subject to regular deep plowing, the size of a scatter and the quality of the finds recovered can change drastically in only a few years.
4. The popularity of field survey and its rapid methodological developments have not been accompanied by parallel developments in theoretical and interpretative frameworks. While scholars have been asking how to recognize settlement hierarchy from survey data and how to make these data comparable (Alcock and Cherry 2004), more recent work has shifted attention away from methodology and the limited range of historical and "processual" questions field survey had been used to answer. Focus is now on the wider archaeological developments in relation to the interpretation of material culture and theories of landscape (Witcher 2006).

International Perspectives

The term villa in modern studies is the cause of some debate, since scholars working on different regions of the ancient world use it differently. In studies focusing on areas such as Roman Italy, villa always refers to mansions of a certain size, displaying notable signs of elaborate décor in the residential quarters, such as mosaic and marble floors and wall paintings. Outside of Italy, in the case of studies on the northern European provinces of the Roman Empire, "villa" is used to label also smaller establishments with little indication of elegant décor, what in effect in the Mediterranean regions is called "farm." The reason for this discrepancy is that these territories annexed by Rome had a very different architectural tradition from the one used in the Mediterranean. Rather than building farms with rectangular plans, Celtic populations built round houses; rather than using masonry and roof tiles, they built in timber. Therefore, when a building in these northern European regions displays a rectangular plan and certain building techniques, scholars see it as sign of either direct Roman presence or of clear Roman influence on local population. In other words, they see in these buildings indicators of Romanization. For this reason, the term "villa," which carries with it a baggage of "Romanness," is used. Differences in modern usage are not limited to these two distinctions. In the context of studies on the eastern provinces of the empire, "villa" is commonly used to indicate particularly grand townhouses, which in size and décor outdid the normal scale found in upper-class urban dwellings. The correct nomenclature for such buildings in the Roman context is *domus*.

Future Directions

In future years, the regular application in excavations of a range of scientific techniques which have become more affordable (e.g., paleobotanical analyses, isotope analysis of bones and teeth, DNA) will yield a wealth of new information on the production of farms and villas, the standards of living of their inhabitants, and the environmental changes caused by the establishment of farms and villas in the countryside (deforestation, reclamation of marshes, and the like) or natural environmental changes which affected these human

settlements. As an example of the new insights gained from DNA studies, one can cite the Vagnari/S. Felice project in southern Italy, focusing on a Roman village and villa which in the imperial period belonged to the emperor. Analyses conducted on the human bones from the many burials excavated in the necropolis have revealed that most of the workforce on this estate was born locally, whereas ca. 25% came from other parts of the empire (http://www.ed.ac.uk/history-classics-archaeology/classics/research/research-projects-ii/vagnari).

Scientific analyses coupled with powerful computing tools, such as geographic information system, are offering effective ways to model and analyze ancient landscapes, allowing to grasp issues about degree of connectivity between sites, location of natural resources, and settlement hierarchy, among other issues.

After decades of attention devoted to villas, both in archaeology and ancient history, attention is now shifting to properly studying the lower stratum of rural dwellings, the farms and farmsteads. Questions about the spatial and material qualities of this lower rural domestic architecture, the rural exchange systems, and the type of interaction between humans and the surrounding environment can be properly answered only through excavation. Despite the fact that thousands and thousands of farms and farmsteads have been located in field surveys, new understandings will come in the future as some investigators are leaving the "allure" of excavating rich villas and turning to understand how the majority of the ancient population lived. The Roman Peasant Project (http://www.sas.upenn.edu/romanpeasants/), for instance, which aimed at investigating the "lived experience of lower-class rural dwellers" (Bowes et al. 2017, p. 172) has identified the first archaeological data for convertible agriculture for the late Republican/early imperial period. These data are very important, since they show intensive use and careful management of the land also at sites at the lower end of the rural settlement spectrum. In addition, the project's results challenge the idea that intensive/extensive land use relates in a straightforward manner to dense/sparse rural settlement patterns, and this has implications for the interpretation of field survey data (Bowes et al. 2017).

Introduction

Mediterranean archaeology has been a territory of intensive methodological experimentation, simulation, and scientific visualization for digital applications in archaeology over the past 30 years. New archaeological discoveries, broader and more intensive archaeological surveys, and multi-stratified sites in need of interpretation and dissemination all demonstrate the need to embrace different and innovative methodological approaches for the reconstruction of the past. The Neolithic site of Çatalhöyük in Turkey, the Paleolithic caves of Lascaux in France, the megalithic temples of Malta in the 1980s and 1990s, and the Acropolis in Athens, for example, turned on a more focused attention to the difficult relation between archaeological evidence, the site, and its perception in present and past societies, through visualization and reconstruction processes. The potential to see and study sites not just through their archaeological evidence, the material culture, but also by their hypothetical original aspect generates new questions and interpretation issues. Debates on representation, multivocality, processualism, and post-processualism (Hodder 1982, 2001) created an important methodological premise to the most advanced use of digital representation and visualization in archaeology. Those debates questioned the authenticity of the digital workflow and its ability to produce virtual models without always having the ability to validate them. Sites were no more considered as

frozen snapshots of the past, but diachronic models, digital interactive environments, and dynamic processes. A specific focus of digital representation on Mediterranean archaeology at the dawn of the computing "big bang" is explainable by the concentration of international multidisciplinary research projects in this area with a more specific emphasis on methodologies of representation and communication, beyond the traditional archaeological report. The use of virtual technologies for visualization opened new and unexplored gates in archaeology, creating a strong connection between interpretation and communication processes.

Definition

Scientific visualization in archaeology includes all the digital processes of computer graphic rendering and simulation involving data, models, and spatial information produced by different integrated technologies of data capturing, virtual reconstruction, and visual communication. Data capturing concerns the digital documentation of objects, sites, and landscapes; virtual reconstruction and visual communication regard the final digital output of archaeological models and data and their social interaction with the public and the community of scholars. The final goal of visualization is the performance of digital data at different levels of analysis, interpretation, and modeling. For example, visualization and data processing in the archaeological fieldwork can come from different technologies such as remote sensing, laser scanning, digital photogrammetry, or computer vision. But visualization can be also generated by computer graphics, animation, or real-time renderings such as virtual reality systems, Web, or cyberspaces online (e.g., virtual communities such as Second Life). A first level of visualization is identifiable during the observation and documentation of the archaeological evidence: for example, in an excavation area or in landscape survey. A second level comes from the virtual reconstruction of archaeological models according to their hypothetical colors, materials, textures, contexts, and shapes. It is important to note that the major part of the visualization projects at the beginning was addressed to digital reconstruction and not on the documentation (Forte and Siliotti 1997; Forte 2000). The reason is that it was much easier in that phase to produce models without very analytical studies on site documentation and on validation of archaeological data.

Historical Background

In the field of digital applications and visualization technologies in archaeology, it is possible to distinguish three main categories: digital documentation, virtual archaeology, and cyber-archaeology. Digital documentation regards all the technologies of data capturing (i.e., laser scanners, remote sensing, photogrammetry, computer visions) and the related visualization of these data. It is the bottom-up phase of archaeological research and it is focused on archaeological evidence: artifacts, ecofacts, sites, and landscapes.

Virtual archaeology was born at the beginning of the 1990s (Forte and Siliotti 1997; Barceló et al. 2000; Forte 2000) with the purpose of virtually reconstructing the past by means of digital (static) graphic renderings. 3D Models were produced with a high level of photorealism, including textures, colors, and geometrical details (Forte and Siliotti 1997). Cyber-archaeology characterizes more specifically this millennium with a focus on interactive models, virtual reality, serious games, and simulation environments.

The first important experiment of digital visualization in archaeology was the reconstruction of the Paleolithic caves of Lascaux in southern France, carried out by Benjamin Britton in the 1990s (Britton 2001). A head-mounted display (HMD) connected with two personal workstations comprised the system: the users dressing the HMD were able to make a virtual imaginary trip into the Paleolithic caves. Another digital experiment simulation was "Virtual Petra" at Brown University (Shape Lab). The scope of this simulation was the reconstruction of the Great Temple at Petra in relation to both archaeological artifacts and stratigraphy (Vote et al. 2002).

Later, the use of visualizing technologies substantially increased, thanks to wider use of personal computers. This technological phase was more oriented to the theatralization of the digital content in virtual environments, virtual theaters, virtual rooms, and immersive visualization systems. In this category, projects like NUME (CINECA, Bologna) and Rome Reborn (UCLA, Los Angeles, and University of Virginia; Frischer 2008) were developed in the late 1990s. NUME (New Electronic Museum of the city of Bologna; Bocchi et al. 2000) was aimed at the historical reconstruction of Bologna, in different phases starting with the twelfth century. Rome Reborn focused on a detailed urban and architectural reconstruction of Rome in 320 CE with a strong emphasis on the monumental and topographical aspects of the reconstruction (Frischer 2008).

At the beginning of the twenty-first century, major attention was paid to applications able to involve users simultaneously and to increase the degree of immersivity. One of the most advanced systems in this category was the AVIE (Advanced Visualization and Interaction Environment), an omni-spatial visualization device for the collaborative interaction of large-scale heterogeneous cultural datasets using 360° stereoscopic visualization environment (Kenderdine et al. 2010). This specific system was used for the immersive simulation of the Mnajdra Megalithic temples of Malta (Flynn and Liritiz 2005) during the exhibit of Spaces of Mnajdra, in Sydney in 2010.

Other projects, such as VITA (Visual Interaction Tool for Archaeology), were wholly oriented towards the development of collaborative systems integrating different types of 3D data (Benko et al. 2004). In the case of VITA, two users wearing see-through, head-mounted displays and tracked gloves were able to explore a portion of the virtual dig site using tangible interfaces and devices. Lu et al. (2007) designed a computer-aided and collaborative system for the reconstruction of archaeological artifacts, which allowed several archaeologists to remotely reassemble artifacts at the same time. Their research work mainly focused on algorithms assisting the reconstruction and support of multiple users rather than the immersive experience of the collaboration. Hall et al. (2001) explored a mixed-reality system SHAPE which allowed for exploration of archaeological artifacts through augmented reality in the public setting of the museum using head-mounted displays.

One of the first virtual collaborative interaction and visualization for archaeological museums was "The Ancient Via Flaminia Project (Forte 2008)" hosted at the National Roman Museum in Rome (Forte 2008; Pietroni et al. 2007) involving the virtual reconstruction of the Roman landscape along the Via Flaminia (a consular road connecting Rome to *Ariminum* in North Italy). The main focus of this application was the Villa of Livia (Figs. 1, 2, and 3), spouse of the Emperor Augustus, a monument virtually reconstructed integrating digital documentation by 3D laser scanning (Fig. 4) and architectural modeling. In this case, the users are able to explore collaboratively the virtual monument using 3D avatars.

Lately, the most advanced use of visualization system in archaeology is tele-immersion (Forte and Kurillo 2010): multiple users from different locations, as human avatars, can share the same cyberspace and operate in that environment almost as a real space. The primary goal of such collaborative frameworks is to facilitate immersive real-time interaction among distributed users. Collaborative applications must provide a communication channel to allow users to verbally communicate and interact with the data. One of the most interesting experiments in this system concerns the reconstruction of the excavation process, and the first case study was the Neolithic site of Çatalhöyük, Turkey (Forte et al. 2012). In this case, all the layers recorded by laser scanner, artifacts, GIS layers, and databases are shared in the 3D space (Figs. 5 and 6).

Key Issues/Current Debates

In the digital era, interpretation, reconstruction, and communication of the past are based on methods and technologies of visualization. This new era of visualization raises new research questions and concerns in relation to the representation of archaeological data in situ, during data

Visualizing Mediterranean Archaeology, Fig. 1 3D virtual reconstruction of the south part of the imperial Villa of Livia

Visualizing Mediterranean Archaeology, Fig. 2 The virtual Villa of Livia: archaeological evidence recorded by laser scanning and in transparency reconstruction of the atrium (first–second century CE)

collection, and in the interpretation phase. A big difference between what happens today in the domain of cyber-archaeology and the past archaeologies is that nowadays almost the entire workflow of data collection and visualization is digital, while in the past, it was mostly analog (Forte 2010a, b). The outcome of this phenomenon is that enormous quantities of archaeological data are born digital and they continue to evolve in digital environments, computers, labs, networks,

Visualizing Mediterranean Archaeology, Fig. 3 The avatar of Livia in the cyberspace of the virtual villa

Visualizing Mediterranean Archaeology, Fig. 4 Laser scanning model of the building 77 at Çatalhöyük (a Neolithic house)

and the Web. In fact, there is a substantial difference between digitizing analog information (e.g., scanning a photograph from a book or a printed map) and capturing data in digital format (i.e., by means of a 3D laser scanner). In the first case, there is a mediation analog-digital since the data are translated by two very different ontologies; in the second case, data are digitally generated directly on site.

Digital visualization and empirical data can have a dichotomous relationship if the methodological process is unclear and not transparent. In other words, a virtual reconstruction of a Neolithic house, for example, could be spectacular and photorealistic but also totally fake if not integrated within a consistent and scientific workflow of transparent data (maps, on-site documentation, databases, etc.). Therefore, authenticity,

Visualizing Mediterranean Archaeology, Fig. 5 3D visualization of the archaeological informative system of Çatalhöyük (B77) – 3D Digging Project

Visualizing Mediterranean Archaeology, Fig. 6 3D visualization of a Neolithic house at Çatalhöyük integrated with the GIS database

representation, validation, transparency, and other related factors pushed the community of archaeologists to discuss about standardization, guidelines, and best practice in the realization of digital archaeological models (Ryan 2001).

One of the first initiatives in this debate was the ICOMOS Ename Charter for the Interpretation and Presentation of Cultural Sites (http://www.enamecharter.org/initiative_0.html; Callebaut et al. 2002), aimed at analyzing problems of representation and communication of archaeological sites. Article 2.4 of the Charter reports that "Visual reconstructions, whether by artists, architects, or computer modelers, should be based upon detailed and systematic analysis of environmental, archaeological, architectural, and historical data, including analysis of written, oral and iconographic sources, and photography. The information sources, on which such visual renderings are based, should be clearly documented and alternative reconstructions based on the same evidence, when available, should be provided for comparison." Another initiative, CVRO (Cultural Virtual Reality Organization) was launched in 2001 (Frischer et al. 2002) with the scope to standardize and validate 3D models in virtual archaeology (Frischer et al. 2002: 9). Even if this initiative was unsuccessful, it pointed out some important methodological issues in digital visualization and representation. A more consistent and international initiative was the London Charter (Beacham et al. 2006; Bentkowska-Kafel and Denard 2012). The introduction to the Charter states: "The London Charter for the use of 3-dimensional visualization in the research and communication of cultural heritage seeks to establish what is required for 3D visualization to be, and to be seen to be, as intellectually rigorous and robust as any other research method. The initiative has to be seen in the context of what has become a constant burning issue in 3D visualization applications to cultural heritage: "transparency" (http://www.londoncharter.org/introduction.html)". The last initiative, named the Seville Principles, has tried to reconnect and update the former initiatives: "The spectacular growth of cultural tourism and the amazing technological advances in recent years have led to the development and implementation of a myriad of projects to investigate, preserve, interpret and present various elements of archaeological heritage using computer-based visualization. These projects have demonstrated not only the extraordinary potential of computer-based visualization but also its many weaknesses and inconsistencies. Therefore, there is a clear need for a theoretical debate with practical implications to enable heritage managers use the best that new technology can offer them in this area while minimizing its most controversial applications. In short, some basic principles must be established to govern practices in this growing field" (http://cipa.icomos.org/fileadmin/template/doc/PRAGUE/096.pdf). Good selection and standardization of these basic principles is very difficult to achieve. All of these initiatives recalled the core of the debate: the scientific validation of the workflow of data producing any process of visualization, representation, and reconstruction. There is no visualization without reconstruction and data integration. In addition, this workflow has to be transparent, accessible, and shareable in order to comprehend the complexity of the digital hermeneutics. Transparency is an important factor in relation to the peremptoriness of virtual reconstruction: once a model is made by digital rendering, one does not offer alternative views to its interpretation. For this reason, it is important to keep track of all the steps undertaken for its production.

International Perspectives

The biggest change in archaeological visualization in the last decade was determined by the evolution of digital technologies and more advanced methods of data capturing and simulation. If the 1990s were characterized by a great development of virtual archaeology (VA), high-resolution static models made in computer graphics, the third millennium is characterized by cyber-archaeology (CA), whereas the models are dynamic and the interpretation is based on the interaction between users and virtual environments.

In cyber-archaeology, data are digitally captured in the field by different 3D technologies

(e.g., laser scanners or photogrammetry), immediately visualized by tablet PCs or mobile computers, post-processed in laboratories for further analyses, and finally shared and again visualized on the Web or in virtual reality systems (Forte 2010a). This new and fast hermeneutic cycle generates new research questions and simulations and increases quality and quantity of information. The visualization speed in this new digital hermeneutic cycle is impressive: data are born visual and grow and spread out visually. In CA the entire simulation process is interactive and, in 3D, can process data individually or by a collaborative network or through virtual communities.

Going back to the historical background on the main topic of visualization and Mediterranean archaeology, it is interesting to note that there is a link between the great discoveries of the nineteenth century and the first experiments of visualization and representation. In fact, the first most important excavations in the Mediterranean region (e.g., Egypt, Greece, Italy, Middle East) made several archaeological sites very famous worldwide. Consequently, when the new potential of digital visualization emerged, these sites were the first to be virtually reconstructed and represented in their original hypothetical context (Forte and Siliotti 1997).

Future Directions

The involvement of digital visualization technologies in archaeology is consistently growing; it is possible to estimate that in the near future, most part of the archaeological fieldwork, survey, and on-site research will be based on real-time visualization. Real-time visualization means that all the data are processed simultaneously and the results are immediately available, visible, and interactive on-site and by different communities of users. This approach involves a strong interdisciplinary effort in the integration of different technologies but also in the methods of survey and excavation. This encompasses a deep transformation of archaeological theory and method and generates a new digital hermeneutics for archaeology. If the ontology of data, format, dimension, quality, and quantity changes, the interpretation process is different as well as the reconstruction and communication of the past. The next possible revolution in this domain is in the collaborative systems: in the virtual communities and in the co-participation of many different stakeholders and content managers. The former research in visualizing archaeological data was mainly focused on specific applications and not so much on revolutionary methods for studying and communicating archaeological data. In the future, stronger and distributed interdisciplinary efforts will be concentrated on new and different ontologies of data and on the systematic use of "mediated" digital documentation (laser scanners, remote sensing, and so on). Mediated and remote tools of investigation operate almost in real time: it means that when a laser scanner records millions of point clouds (Fig. 4), or a stratigraphy (Fig. 7) is generated by computer vision in a tablet PC, the operator/the archaeologist is still there, comparing digital data on a screen and "real" data on-site. In other words, this is the domain of cyber-archaeology, whereas visualization is a performing activity and generates non-predetermined simulations.

A good example is the Çatalhöyük Research Project at the Neolithic site of Çatalhöyük, Turkey (Forte et al. 2012). The site, dating from 7400–6000 BCE is made up of two settlement mounds: Çatalhöyük East and Çatalhöyük West. Çatalhöyük East consists of 21 m of Neolithic deposits. Çatalhöyük West is 6 m high and is almost exclusively Chalcolithic (6000–5500 BCE). Furthermore, the two mounds span 2000 years and indicate a high degree of continuity though time: the house is the social-cultural pattern of the system, ritual space, and domestic and symbolic space. The site was inscribed in the UNESCO World Heritage list in 2012.

An experimental project of 3D archaeology and real-time visualization is ongoing since 2009 with the collaboration of different international teams. The main scope the project is the three-dimensional digital reproduction of the entire archaeological excavation visualizing and interpreting structures, artifacts, and stratigraphic

Visualizing Mediterranean Archaeology, Fig. 7 3D visualization of a micro-stratigraphy at Çatalhöyük with a selection of archaeological objects

layers. All fieldwork activities are based on 3D data recording by 3D laser scanning, digital photogrammetry, GIS, and remote sensing. This workflow involves the following stages: 3D learning, 3D digging-data recording, and 3D communication and reconstruction. The creation of an innovative digital workflow entirely three dimensional (from the field to the virtual reality) represents a revolutionary process for archaeological interpretation. This approach makes the excavation process, which removes physically all the spatial relations between layers and artifacts virtually "reversible." This work allows the complex stratigraphy of the site to be explored, analyzed, and interpreted, thus promoting new questions about site processes.

After the fieldwork, all the data are post-processed by TeleArch (Fig. 8), a 3D virtual collaborative system (see an example here: http://tele-immersion.citris-uc.org/sites/ti6.citris-uc.org/files/ti_archeology.wmv) developed by the University of California, Merced, and by the University of California, Berkeley. The visualization and integration with TeleArch represents the final step of the digital workflow, starting from the archaeological fieldwork (data capturing), post-processing of models (meshing of point clouds), and digitalization of drawings and outlines to a GIS format. Once all the datasets are in TeleArch, it is possible to elaborate the 3D data in a collaborative way. At this stage, the simulation stimulates new feedback from the operator who can interact with models and data identifying new features not identifiable otherwise. The regeneration and simulation of 3D models in a cross-data platform can stimulate new interpretations and assist the research in the validation of the previous ones. In archaeology, this stage of data collection is crucial since during the excavation, a relevant amount of information is removed or destroyed during the digging procedures.

In conclusion, the future for digital visualization in archaeology is very challenging and not easily predictable, given the revolutionary speed at which digital technologies develop. Visualizing will mean interacting in real time with models, data, virtual reality systems, and simulation environments; visualizing will be a digital interactive

Visualizing Mediterranean Archaeology, Fig. 8 TeleArch: Teleimmersive Archaeology system installed at the University of California, Berkeley

performance with a high degree of embodiment for all the users and communities involved. The concept itself of digital visualization in archaeology has changed enormously in the past 30 years: originally involving the graphic rendering of static pictures and then the re-elaboration of dynamic models and environments created by user's avatars. It now includes a digital hermeneutics cycle generating new knowledge not in the reconstruction of a single past but in the simulation of possible pasts.

Volcanic Activity

Felix Riede
LAPADIS – Laboratory for Past Disaster Science, Department of Archaeology and Heritage Studies, Aarhus University, Aarhus, Denmark

Introduction

When measured on the timescale of a human lifetime, volcanic eruptions are – in most regions of the world – relatively rare phenomena. However, over historical, archaeological, and evolutionary timescales, volcanic eruptions occur frequently, and they do so often in areas populated by humans. Nearly 10,000 volcanic eruptions are known from the Holocene alone (Siebert et al. 2010), and more than 2000 such events are known from the late Quaternary. Most volcanologists consider these numbers to be severe underestimates of the actual number of eruptions that have taken place. Volcanic activity has thus been a facet of human life from even before the evolution of the lineage *Homo* in the tectonically and volcanically turbulent landscapes of Eastern Africa (King and Bailey 2006). This entry considers the breadth of these interactions illustrated by a series of case studies, which together highlight the salient features of the relationships between humans and volcanism (see also Grattan 2006; Cashman and Giordano 2008; Riede 2016).

Considerations of volcanic activity in archaeological contexts can broadly be divided into two categories: (1) volcanic eruptions and their fallout as temporal markers and (2) volcanic eruptions as causes or catalysts for bio-cultural change. It is the latter aspect that has generated most controversy, but this entry suggests that the two can, should, and are increasingly being combined under a framework that takes account of past human vulnerability in a way that is sensitive both to the physical and the political, social, ecological, and historical constellations of the affected species and/or societies.

Definition

Volcanic activity ensues when molten rock (magma) is extruded onto the surface of the Earth; lava, pyroclastic materials, and/or volcanic gases erupt through an opening in the crustal surface termed a vent, and each of these types of ejecta constitutes a hazard to people living nearby (e.g., lava and pyroclastic flows, mud avalanches) as well as at some distance (gases and ash fallout). Volcanic activity is chiefly the result of plate tectonic activity (Fig. 1). Consequently, the vast

Volcanic Activity, Fig. 1 A model of the Earth's mantle and the different volcanic systems

majority of subaerial as well as submarine volcanoes are located along plate boundaries, for instance, along the so-called Ring of Fire that frames the Pacific Ocean. Here, continental plates either converge (subduction zones) or spread (rift zones) from each other, and both processes can lead to volcanic activity. Volcanoes can also be fed by so-called mantle plumes, which are accumulations of magma at unusually shallow depths in the Earth's mantle. These features create volcanic "hot spots" (e.g., Iceland, Hawaii, the Eifel region), which often persist over very long times and can rapidly build up critical masses of magma. These subterranean blowtorches burn through the mantle and are responsible for some of the world's largest volcanic provinces (e.g., flood basalts) and most massive eruptions.

Volcanic activity has a plethora of faces, ranging from the gentle and barely noticeable extrusion of gas bubbles in picturesque water-filled craters to cataclysmic super-eruptions that affect climate on a global scale. The products of volcanic activity – for instance, the light and bubble-rich pumice and the durable basalt – have been used in many periods of prehistory and history to fashion tools and as building material. The focus of this entry is the volcanic eruptions themselves, which are commonly rated using the Volcanic Explosivity Index (Fig. 2; Newhall and Self 1982). This semiquantitative scale is similar to the better-known Richter scale for earthquakes in that it is logarithmic and it amalgamates several eruption parameters (volume ejected, plume height, eruption duration, and impact on weather systems and climate).

Volcanic Activity, Fig. 2 Schematic of the Volcanic Explosivity Index (VEI) with examples of past eruptions that have impacted human societies mentioned in the text

Alternative schemes of classification employ more rigorously quantitative measures of eruption magnitude and intensity. Just like volcanism takes many forms, so do the interactions of volcanic activity with human societies vary along a multitude of intersecting axes – volcanic, topographic, technological, economic, religious, and communication-related (Blong 1984; Riede 2015).

Historical Background

Volcanoes as destructive and productive geological agents have long fascinated scholars of natural history. Volcanic eruptions also hold a special place in the history of archaeology. The eighteenth-century rediscovery and subsequent excavation of the ancient Roman towns of Pompeii and Herculaneum in the shadow of the still active Vesuvius and the vivid description of their destruction in AD 79 by Pliny the Younger have captured the attention and imagination of antiquarians, archaeologists, and the public alike (Sigurdsson 1999). Pompeii's morbid allure – a par excellence example of dark geo-cultural heritage – has made it one of today's most visited archaeological sites in the world. Although tragic for the inhabitants of these places, the preservative effect of the ashfall has been a boon to archaeology, allowing for reconstructions of Roman life with unprecedented detail. Similarly spectacular and at times macabre finds of buried settlements and their inhabitants are rare elsewhere in the world and from other periods, but by no means unknown. Indeed, recent work around Mount Vesuvius has revealed evidence of similar or even larger eruptions that buried earlier prehistoric hamlets and fields in the area. Likewise, the Bronze Age settlement of Akrotiri on Santorini in the Aegean Sea – buried by the cataclysmic Thera eruption (1600–1627 BCE) – also ranks among the most comprehensively researched archaeological sites in the world. In the Americas, the buried village of Cerén in El Salvador and Tetimpa in Mexico, for instance, have also provided incredibly detailed snapshots of past life. Much further back in time, the occasional Paleolithic site covered by ash fallout has also been discovered, and key episodes in deep prehistory were likely affected in direct or indirect ways by volcanic activity: The first dispersals of hominins out of Africa was, at the almost two million-year-old locale of Dmanisi in Georgia, stopped short by a volcanic eruption; early *Homo sapiens* may have experienced a severe genetic bottleneck following the Toba super-eruption; the fate of Neanderthals and early European modern humans may have been affected by a paroxysmal eruption at the Phlegraean Fields in Italy whose fallout ash is found as far afield as Russia (e.g., at the site of Kostenki); the recolonization of Northern Europe at the end of the Pleistocene was punctuated by the eruption of the Laacher See volcano in Western Germany; the colonization of Oceania was both delayed by volcanic eruptions, but may at times also have been accelerated by them as their eruption columns may have served as navigational markers for new islands otherwise hidden far below the horizon.

The remarkable discoveries of devastated settlements close to volcanoes do remain exceptional and also illuminate merely one facet of past volcanic activity and its impact on human societies. The sheer destructive forces unleashed in the immediate vicinity of volcanic edifices render it unsurprising that towns and villages were occasionally annihilated and people killed. If, however, recent eruptions and their consequences serve as a useful analogue, then the indirect effects of volcanic events, often at some geographic remove from the eruptive center and articulated through migration and other socioeconomic and sociocultural effects, are much more significant (Table 1). In this vein, several scholars have put forward volcanic eruptions as prime movers or catalysts for cultural

Volcanic Activity, Table 1 The human impacts of recent (twentieth-century) eruptions. Most eruptions entail several forms of response

Impact/response type	N, events recorded	N, people affected
Killed	~250	~90,000
Injured	~150	~16,000
Homeless/ infrastructure damage	~100	~300,000
Evacuated/migration	~250	~5,000,000

changes observed in the archaeological record. Various settlement crises, collapses, and similarly dramatic episodes have been attributed wholly or in part to volcanic activity. Yet, many scholars have pointed out that the precise dating required to distinguish correlation from causation is often not in place and also that volcanic events can stimulate creative and adaptive culture change rather than only lead to collapse.

Key Issues

Establishing whether and how volcanic activity has affected a given human society requires extensive empirical and interdisciplinary efforts. To date, a substantial number of well-research case studies from all parts of the world are available (Grattan and Torrence 2007; Riede 2015; Sheets and Grayson 1979; Torrence and Grattan 2002). What is lacking, however, is a comparative framework within which these case studies reasonably can be evaluated in relation to each other and from which general patterns of vulnerability, response, and impact can be extracted. Volcanic eruptions and their attendant ash (=tephra) fallout are in principle ideally suited to such comparative analyses: Unlike more general arguments about the effects of climate change or most other extreme geological events on human societies, the tephra layers produced by any given eruption act as an archaeologically synchronous time marker that allows for unique event-stratigraphic dating precision. Such so-called isochron layers can then be used to link proximal and distal fallout areas, facilitating the comparative investigation of the dynamics of impact anchored at a common point in time and along a given geographic transect. In this way, the changing impact dynamics among different (but most likely linked) groups are thrown into relief; eruptions and their fallout can serve to bring past communities together through migration, but also separate them via their ecological effects. What is more, the proximal-to-distal dynamics of volcanic hazards also change dramatically, and detailed empirical studies can make solid arguments for the importance of these hazards. To this end, volcanological and disaster scientific studies from present and recent eruptions can serve as a road map to formulating specific and testable hypotheses about how a given eruption in the past may have impacted societies in directly affected areas as well as further afield.

Past Volcanism and Tephrochronology

Temporal control is essential to investigations of volcanic activity and its impact on human communities in the past. The use of tephra in chronological studies is rapidly maturing, and several regions of the world now benefit from robust tephrochronological lattices that link lacustrine, marine, terrestrial, and ice-core records (Lane et al. 2014). Tephra analysis (especially the analysis of non-visible crypto-tephras) is rapidly becoming part of archaeologists' standard analytical toolkit, and linking archaeological sequences directly to the environmental archives that most often contain traces of volcanic fallout is now increasingly feasible. Efforts at collating large datasets of known tephra find localities of particular eruptions require the sifting of literature from a large number of disparate disciplines: geology, volcanology, soil science, palynology, and archaeology. Despite these difficulties, the ever-expanding regional tephrochronological lattices are now beginning to link more and more volcanic provinces together by eruption events detectible in different stratigraphic sequences and often across very large areas. This increasing linkage holds the promise of also being able to better synchronize regional archaeological sequences with each other and with relevant environmental archives (lakes, ice cores, marine sediments, etc.). Yet, methodological problems persist. The geochemical fingerprinting using laser ablation inductively coupled plasma mass spectrometry as a gold standard remains costly, and not all tephras can be readily distinguished even via such high-powered methods. Miscorrelations and erroneous age transfers are possible pitfalls. Furthermore, tephra layers – while themselves not organic – preserve best in stable environmental archives, i.e., many archaeological sites do not offer ideal preservation conditions for tephra. In addition, reworking can lead to the dissolution of

initially discrete tephra layers, creating tephra "zones" of diffuse spread less useful for precise and accurate dating. Yet, tephrochronology is still a young discipline undergoing rapid methodological development and empirical expansion.

Past Volcanism, Vulnerability, and Resilience

Although an ever-increasing number of well-investigated case studies now exist, the potential of volcano and tephra studies in relation to past human vulnerability and resilience is far from exhausted. One issue arising out of the great precision with which tephrochronology can date, in particular, early prehistoric cultural sequences lies in the incompatibility of this event-stratigraphic framework with the usually less precise dating obtained by other means. So, while a given eruption (even a very large one) may have been catastrophic for particular *communities* of early hominids or humans, they may not have left a lasting impact on these as a *species*. Given the generally poor chronological and geographic resolution of Paleolithic cultural sequences, a seemingly unchanging archaeological record can thus mask even significant impacts of a given eruption at a local scale and over short- or medium-term timescales. This problem is further amplified by important differences between proximal and distal impacts and by the difficulty of disentangling the temporalities of effects and impacts. The controversy surrounding case studies such as the impact of the very large Toba super-eruption (~74.000 years ago, Indonesia) with its claimed impact on human genetic diversity and the somewhat smaller but still cataclysmic Campanian Ignimbrite (Y5) eruption (~38.000 years ago, Italy) and its alleged influence on late Neanderthals and early anatomically modern humans in Europe exemplifies these difficulties. It is arguably first from the very late Pleistocene Late Glacial onward that the temporal resolution of the archaeological record begins to be such that the effects on communities rather than species can meaningfully be addressed: In the Late Glacial of Northern Europe, for instance, hunter-gatherer groups living at low population densities were affected by a low-frequency/high-magnitude eruption of the Laacher See volcano located in present-day westernmost Germany. This volcano erupted after a long period of quiescence just after a cold spell that punctuated the otherwise mild and stable Allerød interstadial. The eruption devastated an area of over 1400 km^2 in extent around the eruption site and so preserved archaeological and paleoenvironmental features of that time. This includes some of the richest sites known from this period (e.g., Gönnersdorf) as well as animal tracks, burned woodlands, and a plethora of macrobotanical remains. The nearby River Rhine was dammed up, and when this dam broke, flood waves transported vast amounts of rafting pumice and tephra along the Rhine drainage. Flooding features can be traced as far downstream as the English Channel. The eruption is dated to just under 13,000 years BP, and the tephra fallout from this weeks-to-months-long event is found over large parts of Europe. Yet, no sites in the near-vent region exist that attest to the presence of people in the area immediately prior to the eruption. Indeed, there is one site just north of the area of complete devastation, which may be as little as 200 years younger than the eruption itself. Evidently, people did move back after the event, although their presence in the centuries following the eruption seems to have been ephemeral at best. In contrast to the near-vent area, some regions of medial and distal fallout appear to have been fully or at least largely deserted by people following the eruption. Several sites directly covered by airfall tephra from the Laacher See volcano – after nearly 13,000 years of compression still up to 40 cm thick some 230 km and 10 cm thick some 350 km northeast of the eruptive center – attest to this. The ash fallout likely affected plant and animal populations negatively due to the very low grain size of the tephra particles posing a respiratory health hazard, due to the hardness of the tephra particles dramatically increasing tooth wear and because the tephra was highly loaded with poisonous substances such as fluoride. The seasonal timing of the eruption in late spring/early summer almost certainly further aggravated the effects on animals and plants as seedlings and young animals were less able to withstand the stress generated by the tephra fallout. Although the resolution of paleoenvironmental archives is

rarely good enough to demonstrate such effects as far back in time as the Late Glacial, observations of the effect of tephra fallout on fertility and soil balance in recent times suggest that fallout deeper than 15 cm effectively sterilizes the soil, requiring a lengthy process of regeneration. In addition to these mechanisms, the eruption also affected climate and weather patterns for some time. It likely led to unusual optical phenomena, and extremely loud sounds as well as pressure waves were probably also generated. The eruption column alone would, on a fine day, have been visible over large parts of Europe. The very tangible environmental effects of the eruption combined with its extreme multisensory aftermath for a substantial impact on those groups living at the periphery of the contemporaneous late Paleolithic world. Groups may already have been stressed by the cold phase immediately preceding the eruption, and the abandonment of the affected landscape disrupted important travel, trade, and communication routes leading, in turn, to the isolation of groups in Southern Scandinavia. This demographic isolation appears then to have precipitated notable consequences such as the loss of bow-and-arrow technology, a general reduction of material culture complexity (as measured by the lithic chaine opératoire), and a (perhaps willing) geographic separation from more central continental groups. This separation takes archaeological form in the so-called Bromme culture, the only autochthonous Late Glacial culture in Northern Europe (Riede 2017). As so often in discussions of volcanic impacts on human society, this argument is not uncontested, with issues of chronology and material culture interpretation being central to such counterclaims. Such debate notwithstanding, the brief discussion of this case study serves here to highlight that any arguments about the impact of past eruptions should be sensitive to the kind of indirect (often network- or migration-mediated) "domino effects" of volcanic eruptions. It is as seemingly paradoxical as it is interesting that the strongest cultural effects of past volcanism are often most clearly seen in areas not themselves directly affected by a given eruption and its fallout.

International Perspectives

Volcanic activity does not respect current national border, and, as such, the study of past volcanism almost automatically is given an international dimension, although regional research biases can distort the known distribution of tephra fallout. Even if a given volcano and its fallout affected only one country, it is likely that the indirect effects of this event can be seen and explored in the archaeology of another. It is interesting to note that recent years have seen an increasing interest in past volcanic events specifically in regions that are not volcanically very active today (e.g., Europe north of the Alps). Recent eruptions there and their impact, coupled with the evident impact of other extreme geological events (e.g., tsunamis and earthquakes), as well as advances in Quaternary science and volcanology, have contributed to setting past volcanic activity high on research and funding agendas. The combined power of tephrochronology and of past disaster science in addressing past vulnerability and resilience duly justifies this attention.

Future Directions

Why study past volcanism and its interaction with human societies, and what are the challenges for future research? Volcanism is a relatively rare phenomenon over short timescales, and the number of historical fatalities low. Thus, the data available for evaluating the ecological, economic, and social impact of eruptions in the present and future remain scarce. If, however, we want to better understand the long-term impact of such events on societies, and if there is a causal relationship between long-term patterns of (pre-eruption) vulnerability and (post-eruption) responses and impacts, only archaeology really has access to the necessary temporal perspective (Fig. 3). In addition, the many case studies of the impacts of volcanic eruptions on societies at different levels of economic and political complexity can be used to reflect on and retrospectively analyze the specific constellations of vulnerability that existed among those affected groups (Sheets

Volcanic Activity, Fig. 3 Volcanic eruptions as temporal and analytical markers, especially for investigating long-term patterns of (pre-eruption) vulnerability and (post-eruption) responses. Disciplines such as anthropology, sociology, and history provide insights into the short and medium term, whereas archaeology provides insights into the long term

2012; Riede et al. 2017). Using eruptions and their fallout layer as a chronostratigraphic marker in a dual analytical sense, i.e., as an actual chronological as well as a cultural "time zero," it is possible and imperative to look at the societies before *and* after the event. Given that disaster scientists have long argued that any research into vulnerability and post-disaster recovery must be sensitive to the affected groups' history, such increased systematic attention to past eruptions may be useful for both better understanding the course of prehistory and history (cf. van Bavel and Curtis 2016) and for better understanding volcanic eruptions in general: Disasters, in this perspective, are "revealers" of resilience and vulnerability (García-Acosta 2002: 50). Vulnerability in turn is a composite of economic, ecological, political, and network factors that require broad knowledge of the societies in questions. Ecological and social vulnerability are intimately linked, and simplistic scenarios of the human impact of volcanic events are no longer tenable. Indeed, recent eruptions such as the 2011 Eyjafjallajökull event highlight that eruption size always underdetermines the extent of impact and the particular responses chosen. This eruption was small and the volcano located far away from major centers of human occupation. Yet, many people experienced it as a catastrophe (Lund and Benediktsson 2011). Rather than the geophysical parameters alone, the ways in which an eruption intersects with the economy, mobility patterns, and political and religious structures of the affected groups are vital. It has also been shown that, from contemporary to prehistoric societies, religious worldviews have an important role to play in shaping disaster responses. Vice versa, some theologians argue that volcanic events have played some role in shaping the foundations of major religions either through what has been termed "geo-mythology" or, if loss of life and property are involved, via issues of theodicy (the justification of suffering in light of divine benevolence). Yet, archaeologists generally look first or indeed exclusively toward the climatic or ecological impact of eruption for explaining the cultural changes (or lack thereof) documented in the archaeological record. But can we identify, for instance, the religious repercussions and responses to volcanic activity in the archaeological record, and can we use these as explanatory elements for long-term culture changes? Although contested, some murals at Çatalhöyük in present-day Turkey depict volcanic disasters (Fig. 4). Intriguingly, sites such as Asiklihöyük may be representative of earlier aceramic Neolithic villages affected by ashfall, and the refugees from this or other yet undiscovered sites may be the founders of

Volcanic Activity, Fig. 4 A mural from the famous early Neolithic settlement of Çatalhöyük (Turkey) arguably showing an erupting volcano, possibly Hasan Dagi, and fleeing villagers. The areas marked with vertical stripes are not preserved

Çatalhöyük. Such destruction events may thus have formed an integral part of the early religious systems evident at that site. Similarly, at Arenal in Costa Rica, it has been demonstrated that religiously motivated mobility – pilgrimages – rather than economic or other concerns drew people back to areas devastated by eruptions (Sheets 2011). It seems clear that religious sensemaking structured and continues to structure responses to volcanic hazards, and the climatic and ecological effects of even minor volcanic activity can be greatly amplified by such worldviews (Chester 2005). Much like disaster scientists have called for more attention to history, they have also urged for individual agency to be considered more fully. While at times limited by their data resolution, archaeologists are theoretically well equipped to follow this call. Viewing past societies as internally heterogeneous allows for a more nuanced understanding of past disasters and their impact: Any given volcanic event can be detrimental to some, beneficial to others. Religious movements, for instance, often use such events to drive or suppress social change.

Investigations of contemporaneous disasters, and here especially of volcanic eruptions, have long been the resort of geoscientists. Over the last decades, however, the so-called "radical" approach emerged in partial opposition to the former "dominant" way of studying catastrophes and their consequences (Alexander 2000). The radical school attempts to give more room to human individual and collective agency, history, and politics in assessing the impact of a given event on the impacted societies. In this way, the agenda of radical disasters science matches very well that of many post-processual archaeological approaches, albeit without fully jettisoning the notion of human ecology. If approached from this angle, past disasters hold the potential of bridging the theoretical divide between classic functionalist-ecological and interpretative approaches in archaeology – clearly, no single perspective can amply address issues of vulnerability, impact, and response. Finally, future work could benefit from an ethno-archaeology of volcanic activity and from thinking volcanism through as a form of geo-cultural heritage. While past eruptions are already routinely used as information sources for future eruption scenarios, volcanological, sociological, and anthropological studies of contemporary volcanic events rarely if ever

include considerations of the material aspects of vulnerability and impact beyond basic infrastructural concerns. On a broader scale, interdisciplinary approaches that investigate the twin aspects of vulnerability and impact from the present into the deep past will no doubt yield important insights into the diversity, patterns, and determinants of individual and group responses to volcanic activity and may suggest ways to survive and handle such events in the future (Cooper and Sheets 2012; Riede 2015). If nothing else, past eruptions help us think about potential future calamities in ways that remain constrained by our historical and archaeological evidence base (Donovan and Oppenheimer in press).

Volunteers in Archaeology

Sean Winter[1] and Alice Beale[2]
[1]Department of Archaeology, University of Western Australia, Perth, WA, Australia
[2]South Australian Museum, Adelaide, SA, Australia

Introduction

Archaeology's beginnings in antiquarianism were largely the result of the enthusiasm of amateurs, investigating archaeological sites outside the boundaries of their usual professions. While not true volunteering in a sense, this approach led to many early archaeological studies being conducted in this way and often entirely funded by wealthy benefactors. The development of academic archaeology in the first half of the twentieth century and then commercial archaeology in the second moved archaeology into the realms of a profession and changed the way volunteers were able to be involved. However, archaeology still includes significant contributions from volunteers. The development of these more professional approaches to archaeology has not been without their problems. Indeed it has been suggested that low median wages within the profession are the result of the development of archaeology from what were essentially volunteer roots. For example, Aitchison (2004) has argued that the view still exists that archaeology is something that is conducted for the love of it, rather than for remuneration. Archaeology as a discipline still struggles today to reconcile these ethical issues of successfully combining professional standards and volunteer labor.

Definition

The United Nations (2001) defines volunteering as any activity that is undertaken by an individual of their own free will, for the benefit of others (and themselves) and without expectation of financial remuneration. The use of volunteer labor is generally considered to be ethically acceptable only when it is used for a not-for-profit motive. It is within this broad definition that we discuss volunteering in archaeology.

Key Issues/Current Debates/Future Directions/Examples

Many opportunities for volunteering exist within archaeology and related heritage fields. While the most obvious involve excavations, these opportunities are often rare, places are competitive, and on occasion travel costs have to be met by the volunteer. When excavations for the purposes of research do occur, they are generally undertaken by archaeologists associated with universities or other similar research institutions. Volunteer places are often more readily available with state and local government departments, museums, and historical societies or as part of professional archaeological organizations. Such positions can involve a wide range of tasks not always directly

related to archaeology but can include curating artifact assemblages, undertaking research, or working as guides at heritage places. Institutions like those mentioned are commonly not for profit or rely on grant funding for their research. In such situations, volunteers are essential as budgets rarely extend to pay salaries. In best practice use of volunteer labor, volunteers are considered as unpaid employees, with the same rights and responsibilities as paid workers. Within this paradigm, employers provide training and insurance and cover the out-of-pocket costs for volunteers engaged in archaeological work. However, a study of volunteering within the museum sector (Holmes 2006) suggested that only about half of the institutions who use volunteer labor provide these forms of support.

Archaeological volunteering can be undertaken by people with varying levels of experience, and volunteers can be broken into one of three broad groups. "Students" are those people enrolled in and working towards the attainment of a university degree in archaeology. "Qualified archaeologists" are volunteers with a recognized qualification (usually university level) who may or may not also be working as professional archaeologists. So-called enthusiastic amateurs are people with an interest, but without any specific qualifications, in archaeology.

For students hoping to work in archaeology after graduation, volunteering is a way to gain or refine essential practical skills. Practical training can be rare within structured university classes, and as a result such experience is frequently acquired through volunteer work. Hands-on training is important for teaching both necessary archaeological techniques such as survey and excavation but also essential fieldwork etiquette including not standing too close to the edge of a trench and pitching in with the washing up. A student with a wide range of field experience and a demonstrated ability to work in tough conditions will easily impress future employers over other less experienced candidates.

Often what defines the boundaries of a "volunteer" in archaeology are blurred. While students are encouraged to gain volunteer field experience, in some countries a fieldwork component is a compulsory part of an archaeology degree. In this case what students are primarily engaged in is a program of work experience rather than true volunteering, particularly where they are required to pay to attend field schools or similar. Most students cease volunteering once they receive their archaeological qualification and take up jobs within the profession.

Qualified archaeologists also frequently volunteer their time or expertise. Numerous professional bodies are available for archaeologists to join, and many of these are run by professional archaeologists often in a voluntary capacity. For example, the *World Archaeological Congress* (WAC), formed in 1986, is an international organization run by archaeologists on a voluntary basis to create a global network of researchers and advocate on the behalf of archaeology (World Archaeological Congress 2010). WAC is also responsible for the Archaeologists Without Borders program, which supports disadvantaged countries by funding professional archaeologists working on a voluntary basis to visit and share their expertise (World Archaeological Congress 2009).

Enthusiastic amateurs are members of the public who are interested in archaeology, heritage, or looking for new experiences. There are a number of ethical considerations with using enthusiastic amateurs to conduct archaeological fieldwork. Based on the concept of excavation as destruction, some practitioners question whether it is ethically acceptable to have volunteers with limited experience engaged in processes which effectively destroy the resource being investigated, suggesting that unqualified volunteers may miss vital data due to a lack of appropriate training. However this argument has been countered on a number of grounds, including that no archaeological project is capable of recording all data and that all members of the community have a right to engage with heritage. This argument suggests that so-called amateurs are not simple passive consumers of heritage, but instead have an intrinsic interest in the process and outputs of archaeology. It is within this paradigm that community or public archaeological projects include non-professional volunteers as a standard approach. An example is ongoing excavations at Sedgeford in the UK since 1996. This project is entirely

staffed by volunteers at all levels and is designed to be an ongoing, multidisciplinary, inclusive community archaeological project (Faulkner 2000). All participants, whether qualified archaeologists or local enthusiasts, work on the project as volunteers, towards a common goal, and between 50 and 75 volunteers work at the site each year. The inclusion of enthusiastic amateurs in archaeological fieldwork also provides a labor force that allows large-scale projects that may otherwise be impossible. For example, large-scale field-walking over a wide area can be achieved using volunteer labor. Likewise the inclusion of metal detectorist volunteers in archaeological projects is becoming more commonplace. Volunteers are also employed in an ongoing capacity to help create essential records of at risk archaeological sites. Shorewatch, a UK project started in 1997, relies on the efforts of local communities to manage exposed archaeological sites on Scotland's coast which are under threat from environmental pressures (Dawson et al. 2011). As part of this project, local groups are trained in recording methodology and are provided with recording forms and equipment; this allows groups to record sites as well as monitor their ongoing preservation.

The involvement of local community as has been discussed above can provide both essential labor and a strong support base for archaeology and related heritage fields. In this and other documented capacities, volunteers will continue to play an essential role in archaeology both for the successful completion of individual projects and for the ongoing interpretation and care of archaeological sites and collections.

von den Driesch, Angela

Nadja Pöllath
Bavarian Natural History Collections, State Collection of Anthropology and Palaeoanatomy Munich, Munich, Germany
ArchaeoBioCenter, LMU Munich, Munich, Germany
Institute of Palaeoanatomy, Domestication Research and the History of Veterinary Medicine, Ludwig-Maximilian University, Munich, Germany

Basic Biographical Information

Angela von den Driesch (Fig. 1), née Karpf, was a German veterinarian, archaeozoologist, and university professor. Born in Dresden (Saxony) on

von den Driesch, Angela, Fig. 1 Angela von den Driesch, 1934–2012

July 11, 1934, she grew up in Tegernsee (Bavaria). After graduating from secondary school and attending a language school, she studied veterinary medicine in Munich and Zurich from 1957 to 1962. Two years after obtaining her license to practice veterinary medicine, she received her doctorate in veterinary medicine. When in 1965 Joachim Boessneck (1925–1991) became the first chair of the newly founded Institut für Paläoanatomie, Domestikationsforschung und Geschichte der Tiermedizin (Institute of Palaeoanatomy, Domestication Research and the History of Veterinary Medicine) at the veterinary faculty of the Ludwig-Maximilians-Universität München, he appointed Angela von den Driesch as his assistant. In 1970, she passed her habilitation (German postdoctoral lecture qualification) and was appointed to a professorship at the institute in 1978. After the early death of Joachim Boessneck in 1991, she succeeded him as chair of the institute until her retirement in 1999. She was an active researcher until her death on January 4, 2012.

Major Accomplishments

Angela von den Driesch started her career at a time when the importance of the natural sciences in archaeology and in prehistoric archaeology in particular increased rapidly. Archaeologists realized that archaeozoology among other disciplines could offer valuable data relative to subsistence and ritual practices in prehistoric societies as well as to the local environmental conditions prevailing during site occupation. Through their cooperation in international teams, Angela von den Driesch and Joachim Boessneck essentially influenced the development of archaeozoology as a discipline in Europe and the Near East, which is reflected in their impressive common publication record (Publikationsliste n.d.). Angela von den Driesch participated in excavations in Europe (mainly Germany, Spain, and Greece), the Middle East, Central and Southeast Asia, and Northern and South Africa. As a dedicated teacher, she not only trained young scientists in the lecture hall and the lab of the institute but offered them the opportunity to gain experience abroad in the field.

Since archaeozoology was and sometimes still is considered an auxiliary discipline to archaeology, it certainly was an advantage that von den Driesch was trained as a veterinarian and therefore advocated for archaeozoology as an independent research discipline with study materials and questions as well as methods of its own. In 1976, she published "A guide to the measurement of animal bones from archaeological sites" – a key reference for documenting bone dimensions in mammals and birds, which soon thereafter became the international standard for archaeozoologists worldwide. Her own research centered on the human-animal relationship in the past, but aspects like animal palaeopathology, ichthyoarchaeology (von den Driesch 1994), or ungulate domestication received particular attention (e.g., Peters et al. 1999; von den Driesch et al. 2008).

Her second field of expertise was the history of veterinary medicine (von den Driesch and Peters 2003). Her studies covered pictorial evidence and texts dealing with animal pathologies, the usage

or treatment of domestic animals as passed down by Mesopotamian, Egyptian, Greek, Latin, Arabic, Chinese, and Tibetan artists and authors from early historic to modern times as well as the traditions in veterinarian folk medicine of various peoples – in collaboration with philologists of the respective languages (Maurer and von den Driesch 2006). She was one of only few researchers that combined profound veterinary knowledge with that of the history of veterinary medicine including the diseases of animals evidenced in archaeological sites (e.g., von den Driesch et al. 2004).

When founded, the Munich institute could only rely on a small collection of skeletons so that Boessneck and von den Driesch had to build up a collection for professional archaeozoological use. With their focus on animal remains from prehistoric contexts from Europe, Asia, and Africa, many exotic and meanwhile rare species were needed and could be obtained with the help of zoological gardens and donors or while in the field. First interested in and later a specialist in ichthyoarchaeology, Angela von den Driesch put much effort into the fish reference collection, preparing herself specimens obtained in fish markets from, e.g., the Mediterranean region, Central Europe, North and South Africa, and East and South Arabia. Totaling c. 20,000 skeletons of more than 2,700 vertebrate taxa, the Munich collection today is an extremely valuable and most comprehensive archaeozoological reference.

As many of the so-called small subjects at universities, archaeozoology often has to face the shortage of resources, even to the point of closing down institutions. After Boessneck's unexpected death, this threat became real for the Institut für Paläoanatomie, but von den Driesch could avert it for the time until her retirement. Owing to Angela von den Driesch's farsightedness, the reference collection of the Munich institute was merged with the already-existing Bayerische Staatssammlung für Anthropologie to the new Staatssammlung für Anthropologie und Paläoanatomie München, hence securing beyond her tenure the future of the collections as well as that of the institute. The chair of the Munich institute is now codirector of the state collection.

She was a founding member of the International Council for Archaeozoology (ICAZ) and visiting professor at Pretoria, Cape Town, Phnom Penh, and Madrid, at the *Ecole nationale véterinaire de Toulouse* and Harvard University, Boston. Her merits are also reflected in the honors she received: silver medal *bene merenti* of the Bavarian Academy of Sciences; corresponding member of the German Archaeological Institute, Berlin, and the Austrian Archaeological Institute, Vienna; professor *honoris causa* in the Faculty of Philosophy at the University of Granada; and the Sarton Chair of the History of Science at the State University of Ghent.

W

Walsh, Grahame Leslie

Maria Myers[1] and Cecilia Myers[2]
[1]Melbourne, VIC, Australia
[2]Theda Station, WA, Australia

Biographical Information

Grahame Leslie Walsh was born on the 20th of September 1944 in Roma, Queensland, Australia, and he died on the 18th of August 2007, in Brisbane, Queensland, Australia. Walsh's early years were spent on a Queensland sheep and cattle station where at 13 he was introduced to rock art, an interest he pursued for the rest of his life. After 4 years of high school, he worked as an assistant to a newspaper photographer where he began to develop his photographic skills. In 1977 he became an Aboriginal Site Recorder and later Historic Sites Officer with the Queensland National Parks and Wildlife Service (QNPWS). In this role Walsh undertook systematic recording of cultural heritage sites across Queensland using his own detailed recording system.

In the same year, he began annual visits to the Kimberley area of Western Australia and the Victoria River Downs area in the Northern Territory studying, comparing, and recording the rock art of these two regions.

Walsh established the Takarakka Rock Art Research Centre at Carnarvon Gorge, Queensland in 1984 and began to collate and organize his collection. Supported by the Australian Bicentennial Authority's National Aboriginal and Torres Strait Islander Program, he produced a book on Australia's rock art for the 1988 Bicentenary. In 1989 he took a position as a cultural consultant (specializing in rock art) with the Dreamtime Cultural Centre in Rockhampton, run by Traditional Owners. From thereon Walsh became a full-time independent rock art researcher, and his annual field trip to the Kimberley was extended to 3–4 months.

Between then and his death he focused increasingly on Kimberley rock art, publishing and presenting at numerous conferences, workshops, and private lectures in Australia, Europe, and the USA. He initiated multi-disciplinary rock art research projects and amassed a huge database of sites and associated information. He attracted private funding and a large number of committed volunteers because of his dedication, his mastery of his subject, and his ability to engage others in the possibilities of rock art research, to explain the past.

He was awarded a D.Litt. from the University of Melbourne in 2004. The citation in part read "His contribution to the field of rock art research, management and conservation has been immense,

© Springer Nature Switzerland AG 2020
C. Smith (ed.), *Encyclopedia of Global Archaeology*,
https://doi.org/10.1007/978-3-030-30018-0

and of international as well as national significance." He was awarded a Ph.D. from Griffith University in 2007 for his *Development of Australian Rock Art Recording Methodologies for the Recording and Interpretation of Cultural and Environmental Histories*.

Major Accomplishments

Grahame Leslie Walsh made a significant contribution to the understanding, protection, and documentation of Australian rock art. He accumulated a vast database of Australian rock art over a period of more than 35 years and developed a sophisticated and detailed recording methodology. He collected many traditional stories and myths from Aboriginal informants across the country. He produced several significant publications on Australian rock art.

In the 1970s, Walsh conducted research throughout the Central Queensland Sandstone Belt (CQSB). He worked on cultural site management and developed the first plans to manage visitor access in the Carnarvon Gorge and Mt. Moffatt National Parks by designing and constructing boardwalks and interpretive signage as well as allocating areas for restricted access.

Walsh's documentation of cultural heritage included many other rock art regions in Queensland, and he undertook pioneering recording work in the Mitchell and Palmer Rivers of far North Queensland (1984), the Flinders Island Group of Islands and Princess Charlotte Bay (1983–1986), Lawn Hill National Park (1982–1984), Hook Island, White Mountains (1983), and the Jane Table Hill area of Lakefield National Park (1986).

Walsh's role in the QNPWS encouraged the organization to recognize the importance of protecting cultural heritage sites on lands under its control, changing from its sole focus on natural heritage. Project Duwardi at Lawn Hill (1982–1984) saw Walsh working with Traditional Owners to document the rock art of this area and the development of a management plan for the National Park's cultural sites.

His documenting and photographing of significant rock art across the country culminated in the publication of the highly acclaimed *Australia's Greatest Rock Art*.

Walsh's best-known research was in the Kimberley region of Western Australia. He was the first to recognize and draw attention to the extent, quality, diversity, and significance of Kimberley rock art. His unpublished *Terminology of Australian Rock Art* includes over 900 identifiable elements for Kimberley rock art (Fig. 1). His understanding of these recurring motifs and styles enabled Walsh to develop a relative chronology of Kimberley rock art (Fig. 2). He developed innovative, and sometimes controversial, theories about cultural and environmental changes of the region's past. He produced two major publications: *Bradshaws: Ancient Rock Paintings of North-West Australia* and *Bradshaw Art of the Kimberley*. He also researched widely the most recent Wandjina Period of art (Fig. 3). Through 30 years of research in the Kimberley, he documented thousands of sites, producing an archive and database including over 1.6 million images.

Walsh's Kimberley work included collaborations with traditional elders, anthropologists, archaeologists, paleoclimatologists, geologists, paleobotanists, geomorphologists, and dating experts. Current research in the Kimberley owes much to Grahame Walsh. His work showed the potential for Kimberley rock art to tell the story of Australia's early history and continues to provide a foundation for research in the region.

Awards received include:

- 1985 JP Thomson Medal from the Royal Geographical Society of Australia
- 1990 Joint recipient of the Australian Heritage Award for *Australia's Greatest Rock Art*
- 2001 Winner of the Australian Award for Excellence in Educational Publishing (Scholarly Section) for *Bradshaw Art of the Kimberley*
- Life Member of the Royal Geographical Society of Australia
- 2009 Member (AM) in the General Division of the Order of Australia "for service to the research and preservation of Indigenous art and cultural heritage"

Wang Ningsheng

Beichen Chen
Capital Normal University, Beijing, China

Wang Ningsheng (1930–2014) was a Chinese archaeologist, who worked in the most southwesterly regions of China since the 1960s (Wang 2014). He is regarded as an important figure in Cultural Anthropology and as a pioneer of China's Ethnoarchaeology (Kong and Li 2014; Gu 2014).

Biographical Information

Wang Ningsheng was born in Nanking (known as "Nanjing" after 1979), the capital city of the Republic of China, in 1930. His childhood was spent in the turmoil of the Second Sino-Japanese War (1937–1945), but his parents still managed to make sure that he was educated, especially in Chinese classics and English literature. In 1954, he began his undergraduate studies in archaeology at Peking University 北京大學, supervised by a number of renowned scholars, including Tang Lan 唐蘭 (1901–1979), Su Bingqi 蘇秉琦 (1909–1997), Xia Nai 夏鼐 (1910–1985), and Zhang Zhenglang 張正烺 (1912–2005). In 1960, Wang was transferred to the Central Institute for Nationalities 中央民族學院 (known as the "Minzu University of China 中央民族大學" after 2008) and was sent to Sichuan and Yunnan provinces to carry out archaeological and ethnographic surveys.

Wang Ningsheng's interest in ethnoarchaeology was largely inspired by Gu Jiegang 顧頡剛 (1893–1980), who used the customs of ethnic groups to approach ancient historical and archaeological issues (Gu 1963). Along these lines of thinking, Wang started to write a number of papers based on his surveys in China's southwestern regions. After being transferred to the Institute of History of Yunnan Province in 1964, he decided to turn ethnoarchaeology into his career for the rest of his life.

Just 1 year later, Wang Ningsheng met an important landmark in his career. In 1965, he discovered a large number of human-made markings placed on cliff faces in Cangyuan 滄源 County, Yunnan Province, roughly dated to the late Neolithic period. Together with 2 later discoveries in 1978 and 1982, there are in total 11 locations of "Cangyuan Rock Paintings 滄源崖畫" distributed within a range of 20 km east-west in Cangyuan County (Wang 1985). Most of the rock paintings depict hunter-gatherers and their ritual and production activities. It is notable that, some of the activities, or parts of them, can still be seen in local practice in the present day, which offers a great deal of material for Wang's study of ethnoarchaeology (Yu 2009).

During the 1970s, Wang worked first for the Museum of Yunnan Province and then for the Yunnan College of Nationalities 雲南民族學院 (known as the "Yunnan Minzu University 雲南民族大學" after 2003). Starting from 1983, as a visiting professor, Wang was invited to visit a number of universities in Europe and America, including the University of Pennsylvania and the University of Washington in the USA, the University of Oslo and the University of Troms in Norway, and Heidelberg University in Germany. In addition, he was awarded the title of Honorary Research Fellow by the Institute of the Study of Human Issues in Philadelphia.

Starting from 1990, Wang began writing freelance articles – *Gushi Xinyan* 古史新研 – in the form of columns for newspapers in China mainland and Hong Kong. His final book – *Wang Ningsheng Ji* 汪寧生集 – published in 2014, is a portrait of his life of ethnoarchaeology.

War at Sea Archaeology

Robert S. Neyland
Department of Navy, Naval History and Heritage Command, Washington, DC, USA

Introduction and Definition

"War at sea" today is recognized as armed naval conflict waged by or between sovereign nations or states. Nation-states, like the United States with the world's largest Navy, invest tremendous resources in acquiring, equipping, and manning a dedicated naval fleet for the purpose of carrying out force projection. The modern Navy has a multipurposed mission including display of power by showing the flag, conducting humanitarian efforts, and implementing government policies through blockade of ports, combat, or invasion. From the earliest times, the impetus for development of sea power has been to support maritime trade through protection of the merchant fleet, maintaining access to overseas trade and navigation routes, and even restriction of competitors' trade.

Archaeology addresses the details of naval war as revealed by the artifacts and the global provenance of the archaeological sites. The questions commonly addressed by data recovery from naval archaeological sites concern the specifics of ship construction, weapons, provisioning, and life on board. Frequently finding naval wrecks answers questions specific to a ship's loss and location, which is exceptionally important for ships whose loss is referenced in historic records but the location and cause of sinking are a mystery. Archaeology can address tactical questions regarding how a sea battle would have been fought. Ships lost together in the same naval battle or invasion are interpreted as an underwater battlefield, thus facilitating the study of naval tactics and strategy. It will be possible to answer more theoretical questions regarding the development of navies and the concept of war at sea when a comparative collection of naval sites is acquired through professional underwater archaeological excavation and publication.

Historical Background

Earliest Evidence of War at Sea

Tribal warfare occurred in prehistoric societies, although more governed by ritual than the wars waged by later complex societies. The technological development of basic weapons such as the spear, sword, and bow increased humanity's early warfare capabilities. Maritime cultures used primitive watercraft types including reed craft, dugouts, and skin boats to deploy warriors

and transport captives and booty taken in raids. The earliest evidence of warfare fought at sea comes from Late Bronze Age textual and iconographic materials dating from the late thirteenth to early twelfth centuries BCE. The Tanis stele of Ramses II, texts of the last Hittite King Suppiluliuma II, and texts from Ugarit describe battles with sea raiders who are known to history as the "Sea Peoples." The earliest iconographic image of a naval battle is Ramses III's relief at Medinet Habu, depicting the Egyptian victory over the Sea Peoples. This naval battle and other examples from antiquity illustrate ships engaged in combat with weapons like those used on land – throwing spears, maces, bows, and slings. The Egyptian naval force used one nautical innovation – a grapple and line that was thrown into the enemy ship's rigging and heaved to overturn that enemy ship (Johnstone 1980; Wachsman 1998). Late Bronze Age shipwrecks such as those found at Uluburun and Cape Gelidonya in Turkey substantiate that the swords, knives, and axes carried on ships were similar to those weapons used on land.

One of the first innovations specific to naval warfare was the technique of ramming using a heavy bronze ram to batter the hulls of enemy ships. Evidence for the use of rams comes from iconographic images, war memorials, and naval inventories (Casson and Steffy 1991; Morrison 1995a: 63). The second-century BCE bronze Athlit ram, which contained bow timbers, was found on the Israel coast in 1980, thus providing important archaeological evidence (Casson and Steffy 1991). Another ram came from the Marsala wreck found in Western Sicily. This ram dated to the Punic War of 264–241 BCE and was associated with galley hull timbers marked with Phoenician letters, which the shipbuilders used in the construction process (Frost 1997).

Mediterranean naval warfare was a progressive arms race of ever stronger rams and larger galleys and fleets. Tactical developments in naval maneuvers included the *diekplous* or defensive circle and the *periplous* flanking maneuver. Greeks, Phoenicians, Persians, and Egyptians competed for control of the Mediterranean with their naval fleets. Athens, a city-state, relied on sea power in order to safeguard its essential grain route from the Black Sea and in one summer launched a fleet of 250 oared ships. The Persian King Xerxes attempted to invade Greece with a fleet of 957 triremes, which was opposed by 306 Greek ships. Building and maintaining large fleets required vast economic resources, political and naval organization, and the training of disciplined naval personnel. Battle at sea involved ramming and some naval tactics but continued to be fought like land battles where courage and strength achieved more than tactical skill (Morrison 1995a). Javelins and spears were found on the merchant Kyrenia shipwreck sunk off Cyprus about 300 BCE. These were carried for ship defense or alternatively might represent evidence of an assault on the ship. Land siege weapons such as catapults were deployed on ships in the third century BCE although this has not been confirmed by archaeology (Morrison 1995b). Naval shipbuilders built larger hulls that allowed an increase in the banks of rowers. Rome ultimately built oared ships containing five and seven rower levels. Rome's victory at the battle of Actium, however, curtailed the need for fleets of large naval ships and subsequent fleets consisted of smaller ships used mostly for suppression of piracy and guarding the frontier (Hocker 1995). As Rome expanded into Gaul and Britain, local watercraft were adapted as river lighters, transports, and ferries. Archaeological discoveries from inland rivers and lakes have produced watercraft finds from sites in Germany, Switzerland, France, and the Netherlands. Except for two boats found in Mainz, Germany, that exhibit some Mediterranean influence, none of these inland examples appear to be specifically modified for naval warfare other than being sturdy platforms with an expanded capacity for transport (Arnold 1992; Höckmann 1993; Neyland 1995). As Rome declined, Vandal fleets raided undefended coastal areas. The earliest use of Greek fire in a naval battle occurs from this time and was used by Emperor Anastasius against Ostrogoths in Italy (Hocker 1995).

Chinese naval warfare is mentioned in the Warring States Period from the fifth to third centuries BCE. Although not confirmed by

archaeological finds, documents report the use of grapples, ramming, and halberds. In the third century BCE, the Han Dynasty is credited with development of the stern rudder, the junk-building tradition, and the use of fire to destroy a naval fleet. The Han Dynasty is credited with the use of chemical warfare that was used on land but would also have been available to its navy. Chinese naval fleets continued in use during the later Sui and Tang Dynasties, a period from CE 581 to 907 (Ebrey et al. 2006; Sawyer 2011). India developed strong naval capabilities during the Chola Dynasty from CE 985 to 1042 (Sasaki 2011). Historical accounts describe episodes of piracy and naval conflict between the Arabian Peninsula and Indus region throughout late antiquity and the early medieval period. Alexander the Great built a large fleet to conquer the Indus region during fourth century BCE. His expedition occupied Indus ports and established shipyards in strategic locations (Kervran 1999: 77–83).

Medieval Naval Warfare

Arabs and Byzantines competed for control of the Eastern Mediterranean. In CE 655, at the "Battle of the Masts," Arabs successfully defeated the Byzantine fleet by chaining their ships together to form an unbreakable line. In CE 679, a Byzantine fleet used Greek fire to burn an Arab fleet, and by CE 840, Arab fleets had mastered the use of Greek fire and utilized it to defeat the Byzantine navy. Arab fleets, organized by city rather than kingdom, operated independently but by the tenth century CE employed standing navies with arsenals, officer corps, and state-owned ships (Hocker 1995). Galleys were relatively light and swift and only rarely survive in the archaeological record. Recent excavations in Istanbul discovered four light war galleys, dating from the late tenth to early eleventh centuries CE. The similarities in construction indicate that the state organized and controlled the galley design (Delgado 2011: 188–191).

In Northern Europe warships from archaeological contexts include the seventh-century CE Saxon ship burial at Sutton Hoo in Suffolk, England, and the Norwegian Viking Oseberg, Gokstad, and Tune ships dating from CE 800 to 900. These ship burials contained elegant hulls of overlapped strakes fastened with iron rivets and roves. The royal ships transported warriors for raiding and displayed the prestige of their chiefs. Norse raiders attacked undefended coastal settlements but at times fought sea battles such as the Battle of Svolder in which ships were lashed together as fighting platforms (Christensen 1972; Evans 1986). The recent reinterpretation of a Viking warrior's skeleton from a mid-tenth-century grave in Birka, Sweden, is intriguing for the new analysis found that the previously assumed male is in fact that of a female warrior, which indicated gender roles in Viking warfare were not entirely male dominated (Strickland 2017). Custom in land combat likely applied to the sea.

China's Song Dynasty of the twelfth to thirteenth centuries CE established the first standing navy that at its zenith possessed 20 squadron's totally 52,000 marines. This fleet was equipped with the magnetic compass, paddle wheel watercraft, and gunpowder bombs thrown by trebuchets. The Song Dynasty was seceded by the Mongol Yuan Dynasty of Kublai Khan. The Khan attempted to invade Japan on two occasions using fleets of Chinese- and Korean-built vessels armed with cannon and transporting soldiers and cavalry (Sawyer 2011). Archaeological finds from this invasion reveal the hurried Chinese ship construction; incorporation of Chinese soldiers under Mongol command, weaponry, and supplies for invasion; and the fleet's inability to secure a beach head resulting in its destruction when struck by typhoons (Delgado 2008; Shadbolt 2011). Chinese naval prowess culminated during the Ming Dynasty in the fifteenth century CE when Admiral Zheng He's exploratory fleet was sent out to the southern Pacific and Indian Oceans. Naval shipwrecks have not been discovered, but Chinese merchant ships have been salvaged, including the thirteenth-century CE Quanzhou, fourteenth-century CE Shinan, and sixteenth- to early seventeenth-century CE Ko Si Chang wrecks. Although not naval ships, their construction illustrates that China was constructing sturdy ocean-going

ships (Sawyer 2011; Green 1987a, b). The salvage of the fourteenth-century CE *Maranei* wreck claims to have discovered a hand cannon that predates by 300 years other examples of such weapons (Kaylan 2001). As professional archaeology in Asia expands, more discoveries will be made that will document war at sea in Asia.

The Italian towns of Pisa, Venice, and Genoa built Mediterranean navies to defend their commerce. Sea battles were fought initially against the Arabs, then the invading Normans, and finally with each other. The Genoese and Venetians fought four naval wars, in CE 1253–1284, 1293–1299, 1350–1355, and 1378–1381. Venice was victorious and ultimately dominated the Mediterranean (Lane 1973). During the same period, England and France engaged in constant warfare raiding and fighting for control of sea lanes. The CE 1217 Battle of Dover fought between an English fleet of 40 ships and a French fleet of 80 is credited as the first recorded use of sailing ship tactics. In CE 1340, the Battle of Sluys saw the destruction of the French fleet in a decisive action that gave the English control of the sea during the Hundred Years' War (Lewis and Runyan 1990).

Cogs, caravels, hulks, and carracks were principal types developed for the North Atlantic voyages in the late medieval period. Innovations in the development of fore and stern castles on ships allowed defenders to rain weapons down on attacking galleys. These ships incorporated innovations including the stern rudder, square sailing rig, and navigation with astrolabe, charts, and compass. These ships were built principally for trade but had to also be able defend against pirates and serve a naval function when pressed into service (Rose 2011). The most notable example of a cog is that found in Bremen, Germany; although not a naval ship, it possessed the fore and after castles features necessary for defense during this period. Other cogs have been found in Northern Europe particularly in the Netherlands and Scandinavia (Hocker and Vlierman 1996; Unger 1997). Artillery on ships would play an increasing role and for the first time allow naval ships to battle with one another at a distance.

Exploration and Conquest: Sixteenth-Century Naval Warfare

Archaeological examples from the Mediterranean include the fifteenth-century CE Cavoli ship wrecked on the Sardinian coast while carrying artillery from the Spanish Levant and the Lomellina wreck dating to 1516 (Bueno 1998; Guérout and Rieth 1998). These guns were in part on board as cargo; however, the shape and form of naval guns were not necessarily different than those designed for armies (Martin 2011b). A well-known example of an early English sixteenth-century CE warship is the 700 t burthen "Great Ship" rated *Mary Rose*, built in 1509–1510 period and wrecked in 1545 while engaging the French in the Solent. She carried artillery that included both bronze and iron breech-loading cannon, wrought iron swivel guns located in her fore and stern castles, and a large quantity of shot consisting of stone, iron, lead, and composites of lead and iron, as well as canister shot packed with flint flakes (Hildred 2011). Ships of exploration found in the Americas always carried a complement of wrought iron guns. These voyages were commercial rather than naval, but the distinction between commercial and naval was not clear during much of the late medieval and early modern eras. Japan also used gunpowder and muskets in the late sixteenth century to augment boarding of ships during an invasion of Korea. The Koreans, led by Admiral Yi Sun-sin, defeated the Japanese with superior nautical tactics and the innovative "turtle ship" design (Swope 2005).

How to finance naval fleets and wars was a struggle for the rising states of Northern Europe and the Mediterranean. One method was to defray the fleet cost through regulated piracy. Castile and Aragon hired out their galleys to corsairs in order to defray their ship's maintenance costs. Corsairs were required to leave a deposit with the government in order to compensate damages to friendly parties. State-sanctioned piracy carried the risk of reprisal and war (Mott 2003).

The Ottoman Empire built a powerful navy that dominated the trade and maritime affairs of the Eastern Mediterranean Sea. The Ottoman Navy rivaled that of the city-state of Venice and resulted in the Ottoman-Venetian Wars

(CE 1499–1503). In CE 1571, the Ottomans suffered a severe defeat at the Battle of Lepanto by the Holy League but rebuilt their navy to adequately defend the island of Cyprus as their possession. A late sixteenth-century Ottoman wreck was excavated at Yassiada, Turkey, and provides a comparison of Ottoman ship construction with that of European shipwrights during this time (Pulak 2005). A number of cannonballs found near the wreck might indicate part of a cargo. European maritime nations eventually bypassed the Ottoman control of the land-based trade routes by exploiting maritime routes around Africa to Asia (Scandurra 1972). In the sixteenth century, the North African Barbary states dominated the Mediterranean Sea. Ships were seized and captives taken from the coasts of Italy, Spain, and Portugal, as well as in Northern Europe and even North America. Barbary pirates might have made advances in windward sailing technology that enabled these successes (Godfrey 1974).

Spain, with ships in the Mediterranean Sea and Atlantic and Pacific Oceans, became the first two-ocean navy. It had to arm both ships and forts, thus relied on wheeled guns that could serve in either location. Spain implemented the convoy system to protect its merchant fleet and thus maintain the flow of specie and goods. Galleon construction was government subsidized and regulated. Galleons were designed to be multifunctional serving as warship, transporting troop and supply, and shipping cargo to and from the colonies. England and France's naval strategy was to build smaller and swifter ships that could be used as privateers or for piracy, which were less expensive to construct and maintain (Mott 2003). There are a number of archaeological examples of galleons, several of which are relatively complete such as the Basque whaling ship *San Juan* sunk in CE 1565 and the Swedish warship *Vasa* sunk CE 1628. Galleons were also built in the colony shipyards in the Caribbean and the Philippines. The Philippine-built merchant galleon *San Diego* sunk in CE 1600 after ramming a Dutch ship during battle was discovered and salvaged (Goddio 1994).

Naval fleet actions were fought for control of trade in CE 1508 when a Gujarati/Egyptian force destroyed a Portuguese squadron at Chaul, and the following year CE 1509, the Portuguese destroyed that allied fleet at the Battle of Diu resulting in Portuguese domination of the Indian Ocean. In CE 1582, the Spanish fleet defeated the combined Portuguese, French, and English fleets at the Battle of Ponta Delgada in the Azores. In CE 1588, Philip II of Spain assembled a large Spanish Armada to conquer England. Queen Elizabeth I sent Admiral Sir Charles Howard to counter the Spanish naval force. The Spanish fleet was scattered resulting in a number of Spanish galleys wrecked along the Atlantic Coast of Ireland. This resulted in a number of archaeological sites. One of the largest of Spanish Armada ships was the nave *Trinidad Valencera*. Heavily armed with cannon and small arms, she was both a warship and a transport. The excavation of her remains off the coast of County Donegal, Ireland, revealed numbers of both land and sea guns and weapons such as firepots and a wooden fire trunk for flame throwing. These show how she functioned as an artillery transport but also was designed to fight at sea with cannon and utilize her superior crew size when boarding and hand-to-hand fighting was necessary (Martin 2011a).

Sovereign Navies and Global Empires

From the seventeenth to the eighteenth centuries, increasingly only sovereign states can afford the great expense of a navy. Navies are used by their respective nations to implement global political and commercial objectives. Territorial expansion through colonization was also supported by sovereign navies. Ships were lost in these risky and expensive ventures. Archaeological examples discovered in the United States include the French explorer La Salle ship *LaBelle* sunk in Matagorda Bay, Texas, and the Ribault fleet discovered near Cape Canaveral, Florida (Bruseth 2017; Soergel 2016). Discovery of these sheds light on France's strategies for expansion in North America and the many facets of armament, weapons of conquest, and colonization. Sovereigns of maritime nations were sometimes referred to as the "Master of the Sea," which inferred prestige but also implied the potential to use warfare to establish and protect their maritime realm (Sicking 2003). Competition

between the English and Dutch commercial fleets led to the Anglo-Dutch naval wars in the seventeenth century. The Dutch fleet under Admiral Michiel de Ruyter came up the Thames River and destroyed the British fleet, thus establishing Dutch naval supremacy during the seventeenth century. Naval battles during this period resulted in more ships captured than sunk. Naval guns lacked the power to pierce ships below the waterline, and most of the tactics involved destroying sails, rigging, and men. Tactics still relied heavily on boarding and hand-to-hand combat, but by late century the line of battle strategy was in use. The line of battle was an orchestrated fleet movement along a line that utilizes the advantage of the cannon broadside while not accidentally hitting ships of its own fleet. In order to fight with this tactic, ships of the line were built large enough to withstand the punishing artillery fire during the battle. Naval warfare utilizing line of battle tactics required more disciplined and professional naval officers and crews and strong centralized governments that regulated the design of warships. The stimulus for these conflicts and maintaining expensive navies was commercial competition (Mahan 1918).

The maritime powers of Europe, during the eighteenth century, were continually at war over global politics. Britain, France, and Spain battled over control of trade and the colonies in the Americas. The United States rose out the American Revolution with naval support from Spain and France. Numerous shipwrecks have been excavated from this time period. The 74-gun French-built HMS *Invincible* lost off the Solent in 1758 is an example of a large ship of the line (Bingeman 2011). Other examples include the 26-gun frigate *Machault* and *Bienfaisant* lost in 1760 during the Battle of Restigouche in Canada, as well as the French flagship *L' Orient* destroyed by ADM Nelson during the Battle of the Nile in 1798. Shipwrecks excavated from the American Revolution provide details on the construction, provisioning, and weaponry used during this conflict. Vessels in the United States waters include the British transport *Betsy*, privateer *Defense*, and gunboat *Philadelphia*, all of which were scuttled in separate events (Johnston 1997; Switzer 2005; Broadwater 2005).

The Napoleonic Wars led to a long series of naval battles, the culmination of which occurred in 1805 at the Battle of Trafalgar in which Admiral Horatio Nelson defeated the combined French and Spanish fleets with his naval tactics. The massive 112-gun Spanish Navy ship *Nuestra Senora de la Santisima Trinidad* lost during the battle may have recently been discovered by the Spanish Hydrographic Service (Bilton 2010). After Trafalgar, the British Royal Navy ruled the world's oceans during the nineteenth century. The nascent United States Navy successfully fought ship-to-ship engagements with the Royal Navy during the War of 1812 but lacked sufficient sea power to keep the British Navy from blockading United States ports and raiding the east coast and shores of the Chesapeake Bay. Both British and American navies engaged in riverine warfare in the United States inland waterways. Well-preserved examples include the United States War of 1812 sloops *Hamilton* and *Scourge* sunk in Lake Ontario and gunboats such as the USS *Scorpion* from the Chesapeake Bay region and Lake Champlain (Cassavoy and Crisman 1988; Crisman 2014). The war established the importance to the United States of a blue water navy of sufficient size and quality to defend its shores and commerce and to influence global politics.

The nineteenth century exhibited many advances in ship design, sail and steam power, and weapons. Steam power was used to power paddle wheels as early as the 1810s. It became increasingly reliable, and the steam-powered screw propeller became a more efficient means of propulsion than sail. Riveted iron hulls reduced reliance on timber and permitted construction of stronger and more durable hulls, allowing ships to increase in size. Naval ships by late century developed armored hulls that carried large, accurate guns with rifled chambers that could fire explosive fused shells. USS *Monitor* effectively showed the advantage of the rotating gun turret. *Monitor's* turret and guns have been archaeologically recovered and are under conservation and study. The duel between ironclads CSS *Virginia* and USS *Monitor* marks the change from wooden to iron hulled ships. Innovations were not adopted overnight, wooden ships continued to be used

alongside iron built hulls, and steam-powered ships also carried masts and sails. The American Civil War is a period that saw the first successful use of mine and submarine warfare. Recovery of the Confederate submarine *Hunley* brought the latter nineteenth-century submarine experiments into archaeological focus, showing that many of the twentieth-century submarine innovations had earlier precursors. *Hunley* was an extension of mine warfare, a means of keeping enemy warships off the coast and breaking the blockade (Neyland 2007). Ramming, although a tactic of bygone navies, was successfully used in riverine warfare during the American Civil War. CSS *Virginia* successfully sunk USS *Cumberland* by ramming after pummeling her with cannon shot (Watts 1988). The ironclad ships of Austria and Italy engaged in the first fleet battle of ironclads at the Battle of Lissa in 1866, and interest was renewed in ramming after the Austrian flagship sank the Italian flagship. The last naval ship equipped with a ram was the German ship *Emden* launched in 1908. China's naval battles during the nineteenth century amounted to a series of losses against European steam-powered ships during the Opium Wars of the 1840s and from the Japanese in the Sino-Japanese War in 1894 and 1895.

The subjugation of native peoples by European nations is usually thought of in terms of land battles and armies, but naval power also played its role. Ships were used to transport the armies of colonization and support them with supplies. Ships also engaged in riverine and amphibious operations against native peoples overawing and overwhelming them with the technology and weaponry of ships. Ship guns could shell bands of Native Americans both onshore and in the water as occurred in the Black Hawk War of 1832 and the Seminole Wars fought throughout the first half of the nineteenth century (Trask 2013: 280, 287; Belko 2011).

Key Issues/Current Debates

War at Sea Today

The US Navy's Great White Fleet of 1907 demonstrated United States naval power to the world. These early twentieth-century battleships were steam-powered, steel-armored armed, and mounted large ship-sinking guns in rotating turrets along the centerline of the deck. Steam power made it possible to build these large Dreadnought-class battleships. Twentieth-century navies were pivotal in the global warfare of World War 1, World War II, and the undeclared Cold War. Naval aviation and submarine warfare were the air and undersea innovations that impacted tactics, strategies, and rules of engagement. In 1916, during the Battle of Jutland, seaplanes were launched from seaplane carrier HMS *Engadine*, and in the Black Sea, Russian seaplanes harassed Turkish maritime routes. Aircraft successfully eliminated Zeppelins, engaged in antisubmarine patrols sinking German U-boats, and carried out the first successful torpedo attack on a ship. In 1918, the Royal Navy converted an Italian passenger liner to be the first aircraft carrier (Allward 1993).

The conclusion of World War I resulted in the scrapping of ships under the terms of the Washington Naval Treaty, but by the 1930s nations had resumed rebuilding ships in advance of World War II. The Japanese built the largest ship, the 72,000 t *Yamato*. Battleships would prove to be vulnerable to air power as occurred with the sinking of HMS *Prince of Wales* and *Repulse* and the Japanese attack on the ships at Pearl Harbor. Naval aircraft launched from aircraft carriers protected by a fleet of supporting ships became the effective strategy for naval combat in World War II and thereafter. Aircraft carriers played key roles in the Battles of the Coral Sea, Midway, and Leyte Gulf. There have been numerous archaeological projects to locate and document World War II ship and aircraft losses. Examples of such projects are the United States National Park Service mapping of USS *Arizona*, Naval History and Heritage Command's survey of US Navy shipwrecks lost during the D-Day Normandy Invasion, and NOAA's survey of German U-boats, merchant, and Navy vessels lost during the Battle of the Atlantic off North Carolina coast (Lenihan 1989; Neyland 2009; Battle of the Atlantic 2011). Aviation crash sites, particularly those in the water, have resulted in a specialization in aviation archaeology. Research into twentieth-century ship and

aircraft wrecks focuses on wreck identification, location, loss, and memorials.

Naval aviation after World War II continued to expand with development of jet aircraft, larger nuclear-powered aircraft carriers, and the advent of the use of guided missiles. Ship-to-ship combat has become infrequent since battles occur at greater distances due to naval aviation and missiles. Submarines were used effectively during both World Wars against enemy naval ships but principally took their toll on merchant shipping. These were first diesel powered but during the Cold War were nuclear powered, thus enabling them to stay underwater for weeks or months. Torpedoes were their main weapon of attack during the World Wars, but during the Cold War and today, submarines are equipped to launch dozens of ballistic missiles armed with nuclear warheads. There are ship and aircraft wrecks from the Cold War, but only a few such as those sunk at the Bikini Atoll atomic bomb tests have been archaeologically documented (Delgado 1991; Neyland 2011).

The only major naval conflict that took place after World War II was the 1982 Falklands War. A Royal Navy fleet of 100 ships was dispatched over 7000 miles from Britain to the South Atlantic to protect the Falkland Islands from a takeover by Argentina. British operations were based primarily at sea, which is an element of modern warfare where major sea power nations use their navies as force projection platforms. The Falklands War showed the continued importance of the aircraft carrier but also the vulnerability of modern ships to sea-skimming missiles. Nuclear submarines are an important element for protecting the battle fleet. Twenty-first-century naval operations today are joint land, sea, and air operations. The United States continues to dominate, maintaining a navy with more ship tonnage than that of the next 17 largest navies.

Future Directions

Predictions for future war at sea indicate battles will be fought at great distances using unmanned systems above, on, and below the water. These autonomous systems will both operate independently and be integrated into manned counterparts. War at sea is far more technologically advanced, but many of the casual elements are similar to those of earlier periods – maintaining coastal and national defense, preserving maritime commerce and freedom of the seas and support of military land deployments. These systems have pushed the exploration of the deep sea and are having an impact on the archaeological study of naval vessels, especially those sunk during World War II and the Cold War. Recent deep-sea explorations have found shipwrecks that were previously beyond human reach. The discovery and mapping of USS *Indianapolis* at a depth of 18,000 ft. within an undersea mountain range is a prime example.

The militarization of space by nations for the purposes of surveillance, global positioning, and communications has become an integral part of war at sea. Space operations are as important today as naval aviation was to winning World War II at sea. Synthesis of sea, air, and space warfare will continue as exemplified by annual Navy League's Sea-Air-Space Exposition, which is touted as "the largest maritime exposition in the U.S." (Navy League's Sea-Air-Space 2017). The world's oceans already contain many space artifacts that have fallen out of orbit.

Advances in deep-sea technology are having an emerging impact on the archaeological study of those naval vessels sunk in deep waters; most examples of discoveries are those sunk during World War II and the Cold War. A recent exploration, funded and led by Microsoft co-founder Paul Allen, found and extensively surveyed USS *Indianapolis* at a depth exceeding 5.5 kl (Navy News Service 2017; PBS 2017).

Ward, Graeme K.

Janine McEgan
College of Humanities, Arts and Social Sciences, Flinders University, Adelaide, SA, Australia

Basic Biographical Information

Born in Auckland in 1943, Graeme Ward completed his secondary schooling in Auckland and Wellington. His university studies at the University of Otago included a range of science and arts subjects; he graduated in 1969 with a Bachelor of Arts with a double major in anthropology and psychology. He undertook papers in Prehistoric Archaeology and wrote a thesis in 1970–1971, under the supervision of B. F. Leach, entitled "Obsidian and New Zealand Archaeology: A paradigm for sourcing artifact assemblages using X-ray fluorescence spectrography," and graduated with a Master of Arts (First Class Honors). As an undergraduate and master's student, he was involved in fieldwork throughout New Zealand and in Fiji and in advocating national legislation to protect archaeological heritage.

After employment as an assistant lecturer in archaeology, Ward won a doctoral scholarship in the Research School of Pacific Studies at the Australian National University. He conducted fieldwork in the New Hebrides 1973–1975 toward his doctoral dissertation, *Prehistoric Settlement and Economy in a Tropical Small Island Environment: The Banks Islands, Insular Melanesia* (1979). At ANU, making further use of his training in basic sciences, he collaborated with colleagues to explore aspects of raw material sourcing (e.g., Smith et al. 1977) and in clarifying approaches to the use and interpretation of radiocarbon age estimates and of the intellectual arguments behind sourcing studies (e.g., Ward and Wilson 1978).

In 1972, Ward researched places associated with the chert industries of the eastern Solomon Islands as part of the project organized by R. C. Green and D. Yen. In 1979–1980, he assisted Leach with excavations on Kapingamarangi, a Polynesian outlier in Micronesia, and the following year took leave from his Australian employment to act in the role of Director of the Micronesian Archaeological Survey for the (US) Trust Territory of the Pacific Islands. Subsequently, he was involved in contract research in the Mariana Islands. During his work with the Archaeological Survey, he edited and published several MAS Reports for the Historic Preservation Office.
